Spectral Band Difference Effects for Cross-Calibration in the Solar-Reflective Spectral Domain

P.M. Teillet, G. Fedosejevs
Canada Centre for Remote Sensing
K.J Thome
University of Arizona
Introduction

• For quantitative Earth observation applications to make full use of the ever-increasing number of Earth observation satellite systems, data from the various sensors involved must be on a consistent radiometric calibration scale.

• However, different applications and technology developments in Earth observation typically require different spectral coverage.

• The result is that relative spectral response functions differ significantly between sensors, even for spectral bands designed to look at the same region of the electromagnetic spectrum.
Study Premise

• What is the impact of spectral band differences between satellite sensors on cross-calibration (Xcal) based on near-simultaneous imaging of common ground look targets in analogous spectral bands?

• Given that Landsat-7 ETM+ is well calibrated radiometrically, cross-calibration between the ETM+ and several other sensors was the starting point for the study.

• With spectral band difference effects (SBDEs) on cross-calibration between ETM+ and other sensors in hand, all other Xcal combinations between sensors can be readily examined (in the Landsat-centric spectral domain).
Previous Studies

• Teillet et al. (2001):
  ➢ In 6 solar reflective bands for Landsat-7 ETM+ versus Landsat-5 TM.

• Trishchenko (Trichtchenko) et al. (2002):
  ➢ In red, near-infrared, and NDVI for NOAA-9 AVHRR versus other NOAA AVHRRs, Terra MODIS, SPOT-4 VGT, and ADEOS-2 GLI.

• Steven et al. (2003):
  ➢ NDVI for 15 satellite sensors.

• Rao et al. (2003):
  ➢ ATSR-2 versus MODIS, allowing for SBDEs.
Assumptions

• Temporal:
  ➢ Images acquired under clear sky conditions on the same day.

• Spectral:
  ➢ Spectral bands with analogs to the six solar-reflective Landsat-7 ETM+ bands.
  ➢ Spectral bands well characterized prior to launch and unchanged post-launch.
  ➢ Out-of-band response not taken into consideration.

• Radiometric:
  ➢ Nominal calibration coefficients are being checked.
  ➢ Linear radiometric response over the range of relevant radiances.
  ➢ Differences in radiometric resolution not taken into consideration.
  ➢ Bidirectional reflectance effects not taken into account.
  ➢ Terrain flat and horizontal.
Simulation Methodology

• Simulate spectral band adjustment factors for Reference and eXperimental sensors:
  - Start with calibration test site ground spectrum.
  - Use atmospheric radiative transfer code (CAM5S) to compute $\rho_{iR}^*$.  
  - Use atmospheric radiative transfer code (CAM5S) to compute $\rho_{iX}^*$.  
    ▪ In analogous solar-reflective spectral bands.
  - Calculate band difference factor, $B_i = \frac{\rho_{iR}^*}{\rho_{iX}^*}$.
    ▪ For all pair combinations of ETM+; ALI; MODIS; ASTER; MISR.
• Error in cross-calibration directly proportional to $B_i$.

• Simulate spectral band adjustment factors for NDVI:
  - $\text{NDVI} = \frac{(\rho_{\text{NIR}}^* - \rho_{\text{red}}^*)}{(\rho_{\text{NIR}}^* + \rho_{\text{red}}^*)}$.  
  - $B_{\text{N}} = \frac{\text{NDVI}_{\text{R}}}{\text{NDVI}_{\text{X}}}$.  
• Error in NDVI comparisons directly proportional to $B_{\text{N}}$.  

$$\text{NDVI} = \frac{(\rho_{\text{NIR}}^* - \rho_{\text{red}}^*)}{(\rho_{\text{NIR}}^* + \rho_{\text{red}}^*)}$$  
$$B_{\text{N}} = \frac{\text{NDVI}_{\text{R}}}{\text{NDVI}_{\text{X}}}$$

Results:
SBDEs on Cross Calibration (Xcal): Test Site Comparison

• Without corrections for spectral band difference effects:

- The RVPN calibration site is less susceptible to SBDEs than the NIOB site in almost all sensor Xcal combinations examined.

- For the NIOB site and for the sensors involved, with few exceptions, the spectral content of the scene must be known for accurate cross-calibration based on near-simultaneous imaging.
Results
SBDEs on Cross Calibration (Xcal): Spectral Region Comparisons

• Without corrections for spectral band difference effects:

  ➢ Green is the optimum spectral region for RVPN in that 2/3 of the Xcal combinations are “very good” and the other 1/3 are all “good”.

  ➢ The “poorest” spectral region overall is the NIR for both test sites.

  ➢ For the NIOB site, there are no spectral regions that can be considered “very good” and only the green and red spectral regions have more than a few “good” Xcal combinations.

  ➢ For the RVPN site, the ETM+ band 7 analog spectral region is also to be avoided in the absence of SBDE corrections.
Results
SBDEs on Cross Calibration (Xcal): Sensor Combination Comparisons

- Without corrections for spectral band difference effects:
  - Sensor Xcal combinations involving ETM+, ALI, ASTER and one MODIS band set (bands 3, 4, and 1) are “very good” in the blue, green and red spectral regions for RVPN (the one exception is the band 2 analog band combination of ASTER band 1 and MODIS band 4 where $B_i = 0.985$).
  - Sensor Xcal combinations involving MISR are the most susceptible to SBDEs, with generally “poor” results.
  - There are no sensor Xcal combinations for which the entire Landsat solar-reflective spectral domain yields “good” results in the absence of SBDE corrections.
Results
SBDEs on:
NDVI Comparisons

• Without corrections for spectral band difference effects:

➢ There are a few “very good” cases but, overall, NDVI is highly susceptible to SBDEs, with a percent root mean square difference in BN from unity of 9.4 % across the set of 15 comparisons.
• It is clear from the results that, except for a limited number of cases, sound sensor cross-calibration using common ground targets requires that the spectral characteristics of the common ground look targets used be known.

• Low-cost Xcal methodologies that seek to complement the more accurate calibrations from costly field campaigns should somehow take SBDEs into account.
Concluding Remarks (2/2)

- Spectral data and tools recommended to facilitate cross-calibration between satellite sensors:
  - On-line central repository of:
    - Relative spectral response profiles for as many Earth observation sensors as possible.
    - Well-documented target spectra from surface measurements at key calibration test sites.
  - Tools for easy transformations between different wavelength grids to facilitate comparisons.

- Coordinate central repositories and activities with the Committee on Earth Observation Satellites (CEOS) Working Group on Calibration and Validation (WGCV).
Work in Progress to Extend Study

- Xcal combinations of 17 Earth observation satellites:
  - ETM+
  - TM
  - AVNIR
  - ALI
  - ASTER
  - HRG
  - Ikonos
  - QuickBird
  - AVHRR
  - VGT
  - ATSR-2
  - MODIS
  - GLI
  - MISR
  - SeaWiFS
  - OCTS
  - MERIS

- Scene spectral content: 11 ground targets:
  - Unity reflectance
  - Snow (CAM5S)
  - Railroad Valley playa Nevada
  - Dry sand (CAM5S)
  - Newell County rangeland Alberta
  - Bright vegetation (CAM5S)
  - South Dakota “3M” grass site
  - Niobrara grassland site
  - Black spruce
  - Clear water (CAM5S)
  - Zero reflectance

- Scene spectral content: Examining role of:
  - Different solar zenith angles
  - Atmospheric models
  - Aerosol optical depths

- Landsat-centric spectral domain.

Basic Equations for Raw Data in Solar Reflective Spectral Band i

The image quantized level $Q_i$ (in counts) is related to TOA radiance $L_i^*\ (\text{in Watts}/(\text{m}^2\ \text{sr} \ \mu\text{m}))$ in spectral band $i$ by

$$Q_i = G_i \ L_i^* + Q_{oi}, \quad (1)$$

such that bias-corrected image values are given by

$$\Delta Q_i = Q_i - Q_{oi} \quad \Delta Q_i = G_i \ L_i^*$$

$$\Delta Q_i = G_i \ \rho_i^* \ E_{oi} \ \cos\theta \ / \ (\pi \ ds^2). \quad (2)$$

where $G_i =$ sensor responsivity (in counts per unit radiance),

$\rho_i^* =$ TOA reflectance,

$Q_{oi} =$ zero-radiance bias (in counts),

$E_{oi} =$ exo-atmospheric solar irradiance (in W/(m$^2$ $\mu$m)),

$\theta =$ solar zenith angle,

$ds =$ the Earth-Sun distance in Astronomical Units.
The combination of equation (2) for image data from reference sensor ("R") and another sensor ("X") yields

$$\Delta Q_i X_A = (G_i X / G_i R) \Delta Q_i R = M_i \Delta Q_i R,$$

where

$$M_i$$ is the slope that characterises $$\Delta Q_i X$$ as a function of $$\Delta Q_i R$$.

$$\Delta Q_i X_A = A_i \Delta Q_i X.$$  \hspace{1cm} (4)

$$A_i = B_i \left(\frac{E_{oi} \cos \theta}{E_{oi} \cos \theta}ight)_R / \left(\frac{E_{oi} \cos \theta}{E_{oi} \cos \theta}ight)_X,$$

$$B_i = \rho_{i R} / \rho_{i X}.$$  \hspace{1cm} (5)

$$A_i$$ adjusts other sensor image data for illumination and spectral band difference effects, where $$B_i$$ is a spectral band difference adjustment factor.

The other sensor’s updated responsivity $$G_i X$$ is then given in spectral band i by

$$G_i X = M_i G_i R \text{ in counts/(Watts/(m}^2\text{sr} \mu m))}.$$  \hspace{1cm} (7)

Thus, near-simultaneous data pairs make it possible to use well-calibrated reference sensor image data to update the radiometric calibration of another sensor.
