1.3 Scope of the document

This document is dedicated to the cyclic monitoring report of the SRAL calibration parameters within the Sentinel-3 MPC project. Also a whole mission analysis is given.

It will be distributed during the Routine Operations Phase to the MPC team on a cyclic basis. The MPC team is in charge of its official delivery to ESA and EUMETSAT.
2 SRAL Internal Calibration Monitoring.

2.1 Introduction

The SRAL instrumental calibration is assessed during the mission. Several parameters are monitored and analysed in detail in order to characterise the altimeter performance along the mission lifetime.

Two main groups of calibration parameters are monitored.

The first is derived from the Point Target Response (PTR) calibration in CAL1 mode. The PTR signal follows the same circuitry path as the science waveforms within the calibration loop. The delay caused by the travel through the calibration path can be measured and afterwards compensated in the total range computation. The attenuation suffered by the signal when traveling through the instrument also needs to be monitored and the science waveforms need to be compensated for this power variations. Moreover, there are a collection of other parameters to be checked, such as the PTR width and the secondary lobes features. These CAL1 parameters are produced separately for LRM and SAR modes, as they follow different instrumental paths, and also they are duplicated for Ku-band and C-band. Moreover there are different options for characterising the delay and power of the closed loop signal, such as the PTR maximum power or PTR maximum position.

The second is related to the Instrument Transfer Function, measured by the CAL2 mode. The science waveforms spectra is distorted by the on-board instrumental hardware sections. Therefore, in order to retrieve the original echo shape, we need to compensate for this effect. Several parameters are derived from the analysis of the CAL2 waveforms for characterizing it and dissect any feature along the mission lifetime. The CAL2 waveform is the same for both modes LRM and SAR, but there is a distinction between bands Ku and C.

Additionally, for SAR mode, the two intra-burst corrections are monitored: they are the power and phase progressions within a burst. Science pulses within a burst are to be corrected for these expected variations in the burst. Some characteristics are computed for describing and following up their behaviour along the S3 mission.

It is also of major importance the monitoring of the on-board clocks. The altimeter clock counter, responsible for computing the echo travel time, has a multiplicative impact in the range determination. The platform clock is responsible for the overall platform instruments datation. Their stability and performance are to be supervised along the mission.

Finally, the data coming from the thermistors located in the different sections of the on-board HW (HKTM products), are to be analysed in order to check the relation of any calibration parameters anomaly with the thermal behaviour, and find solutions for modelling the instrument characterisation (for instance orbital oscillations) if needed.

An important remark is to be made: although we can see a certain drift of a specific calibration parameter along the mission, this is not to be considered as a warning for the quality of the science
data, as long as the instrumental calibration is correctly applied during the science data processing. A warning shall be raised in the scenario of a calibration parameter value approaching the mission requirement bounds.

### 2.2 Cyclic In-Flight Internal Calibration.

In this chapter, the monitoring of all calibration modes main parameters is depicted in figures. An analysis of the cycle results is developed in chapter 2.3.

#### 2.2.1 CAL1 LRM

Figure 2.2-34. AutoCal measurements: Corrected – Reference. Averaged over the analysis period.
2.2.5 On-board Clock Performance

The altimeter and platform clock frequencies will be here below depicted and analysed when the USO auxiliary files are available. Their assessment is very important for the identification of the range anomalies causes, all along with calibration parameters such as the PTR time delay, and the datation issues during the mission. It has a multiplicative impact in the final range.
2.2.6 Housekeeping Temperatures

Time series of thermistors temperatures on CAL1 LRM IQ mode over the analysed period.

**Figure 2.2-40.** Second group of Thermistors time series on CAL2 mode. The temperatures are averaged for each calibration product over the analysis period.
2.3 Cyclic SRAL Status Summary

This section is dedicated to a summary of the cyclic performances and status of the altimeter parameters exposed in section 2.2.

For the analysed period, none of the calibration parameters is showing a significant anomalous behaviour. Nonetheless some specific observations are explained here below.

As expected, the Ku band (SAR science main band) calibration parameters performances are better than the ones from the C band. The calibration data dispersion is higher for the C band.

In general, the LRM and SAR performances are similar for a given band (Ku or C).

In Table 2-1 the main CAL1 parameters statistics are detailed.

*Table 2-1. Collection of calibration parameters statistics for all modes and bands covering the whole mission.*

The CAL1 power trend for Ku band is no longer close to -1 dB/yr as at the first cycles of the mission (see section 2.4).

The CAL1 time delay has a decreasing trend, and for the first time in the mission it is getting absolute values over 5 mm/year for the Ku band and over 30mm/year for the C band. This is to be followed in the next cycles.
For the CAL1 width, it is also the first time in the mission having higher absolute values than 6 mm/year for the Ku band, and 50 mm/year for the C band. These cyclic trends have been changing along the mission between positive and negative values.

The thermistors values are showing a stable series over the analysed period, although a bump up of around 0.4 °C is observed at the second half of the cycle.

All these observations are related to the different SRAL calibration parameters during this cycle. We must be cautious by making extrapolations from a cyclic behaviour to an overall mission instrument performance, as it may change from cycle to cycle.

Therefore, a whole mission observation is needed, and is developed in section 2.4.
2.4 Mission SRAL Status Summary

The main L1b calibration parameters series are gathered and plotted in this section, in order to observe their whole mission behaviour. For the sake of simplicity, the C band and the LRM mode have been excluded.

The plotted calibration parameters are:

- CAL1 time delay
- CAL1 power
- PTR width
- Burst corrections (power and phase) and their slopes
- CAL2 waveform ripples shape, plus the waveforms slopes and detrended standard deviations
- Autocal averaged differences and attenuation progression

Also the SAR mode thermistors series is plotted.

Figure 2.4-9. CAL2 Ku waveform standard deviation at each side after compensating by the slope, averaged over the whole mission.

Averaged Autocal differences.

Figure 2.4-10. Autocal measurements: Corrected - Reference. Averaged over the whole mission.
AutoCAL attenuation progression series.

Figure 2.4-11. AutoCAL attenuation whole mission progression for Ku-band. Difference in dB with respect to the previous attenuation value, for each attenuation step.

Figure 2.4-12. AutoCAL attenuation whole mission progression for C-band. Difference in dB with respect to the previous attenuation value, for each attenuation step.
So far the only clear and notable drift observed in the whole mission series is in the CAL1 Ku Power series, where we observe a significant power decay. Anyhow, it has decreased the observed trend in the last cycles. In cycles 8, 10, 12 and 14 the whole mission SAR Ku Total Power trend in absolute values was respectively of 0.89, 0.76, 0.70 and 0.66 dB/year. Hence, we can state a slow stabilisation of this parameter.
Also the PTR time delay has decreased its negative trend. In cycles 8, 10, 12 and 14 the whole mission SAR Ku Time Delay trend in absolute values was respectively of 2.02, 1.65, 1.32 and 1.22 mm/year.

The PTR width for the Ku band has a negative trend around 0.65 mm/year, three orders of magnitude below its absolute value.

The attenuation steps progression in dB is shown in Figure 2.4-11 and Figure 2.4-12, where we can check, for each attenuation step, the delta in attenuation with respect to the previous value in time. The tendencies are visible for specific attenuations in each band case, with small drifts (see colour code at right hand side).

In terms of intra-burst corrections, their slopes along the mission are quite stable. It is visible a slight decreasing of the burst phase correction slope of around 0.5 mdeg/pulse.

The CAL2 parameters behaviour is stable along the mission.

The thermistors data series are generally showing a decreasing slope, as shown in Figure 2.4-13 and Figure 2.4-14, although in the last cycles it is stable.

Finally, the collection of statistics for the main calibration parameters is depicted in Table 2-2 for both modes and bands. Once more we observe the better performance (less standard deviation) of the Ku band with respect to the C band, and the general similar values and trends between modes (with some exceptions such as the time delay slope and the power absolute values).

Table 2-2. Collection of calibration parameters statistics for all modes and bands covering the whole mission.
The long term drift for the time delay and power variables is higher in absolute terms for the Ku band than for the C band, while the standard deviation is always lower for the Ku band. This means that, although the Ku band chain performance is better than the one from C band, the Ku band ageing is faster than the one from C band, probably caused by the more stressed Ku band instrumental operations (e.g. bursts transmission & reception only in Ku band).

The time delay and PTR width in C band have changed to steeper slopes, in agreement with the cycle behaviour (see section 2.3). The PTR width standard deviation for the C band is around 6 times higher than the one from the Ku band, for both operational modes.

As a general observation, we can say that the behaviour of all calibration parameters is nominal. Nevertheless the different values shall be compared to the official S3 mission SRAL instrumental requirements in order to make a final statement. Once they are gathered, the calibration performance check versus requirements will be made, and warnings will be raised accordingly.

2.5 SRAL Dedicated Investigations

This chapter is devoted to the investigations derived from observations along the mission. The on-going investigations results will be updated in each new version of the report; solved issues will be dismissed from the report.

- The flagging of some L1b CAL2 parameters (slope, mean and standard deviation over the slope) is reversed. This issue is not impacting the quality of the science data.

- Some duplicated products have been detected in the MPC ftp site. This situation is to be solved, in order to contribute having a unique consolidated database.
3 Events

No SRAL special events have been observed during the cycle.
4 Appendix A

Other reports related to the STM mission are:

- S3-A MWR Cyclic Performance Report, Cycle No. 014 (ref. S3MPC.CLS.PR.05-014)
- S3-A Ocean Validation Cyclic Performance Report, Cycle No. 014 (ref. S3MPC.CLS.PR.06-014)
- S3-A Winds and Waves Cyclic Performance Report, Cycle No. 014 (ref. S3MPC.ECM.PR.07-014)
- S3-A Land and Sea Ice Cyclic Performance Report, Cycle No. 014 (ref. S3MPC.UCL.PR.08-014)

All Cyclic Performance Reports are available on MPC pages in Sentinel Online website, at: https://sentinel.esa.int
