1 Introduction

This document aims at providing a synthetic report on the behaviour of the radiometer in terms of instrumental characteristics and product performances as well as on the main events which occurred during cycle 38.

This document is split in the following sections:

❖ Section 2 gives an overview on the status of the current cycle
❖ Section 3 addresses the monitoring of the MWR of the current cycle. This section covers the short term monitoring of internal calibration, brightness temperatures and geophysical parameters.
❖ Section 4 addresses the long term monitoring from the beginning of the mission. It provides a view of the internal calibration monitoring as well as two subsections covering the monitoring of vicarious calibration targets and geophysical parameters.
2 Overview of S3A Cycle 042 - S3B Cycle 023

2.1 Status

The Table 1 and Table 2 give a summary of the instrument behavior for S3A and S3B respectively during this period.

2.2 IPF processing chain status

2.2.1 IPF version

This section gives the version of the IPF processing chain used to process the data of the current cycle.

If a change of IPF version occurs during the cycle, the table gives the date of last processing with the first version and the date of first processing with the second version:

3 MWR Monitoring over S3A Cycle 042 - S3B Cycle 023

This section is dedicated to the functional verification of the MWR sensor behaviour during S3A cycle 42 (25 February 2019 – 24 March 2019) and S3B cycle 23 (07 March 2019 – 03 April 2019). The main relevant of the parameters, monitored daily by the MPC team, are presented here.

3.1 Operating modes

The radiometers on-board S3A and S3B have several operating modes listed hereafter:

❖ Mode 0: Intermonitoring (Earth observation)
❖ Mode 1: Monitoring
❖ Mode 2: Noise Injection calibration
❖ Mode 3: Dicke Non-Balanced calibration (100% injection – hot point)
❖ Mode 4: Dicke Non-Balanced calibration (50% injection – cold point)

Figure 1 gives the distribution of the different modes in the data.

![Figure 1: Distribution of operating mode (S3A: left; S3B: right)](image)

The distribution has slightly changed with respect to previous cycle due to update of calibration timeline of the 1st March 2018. Before the update, a calibration sequence is 9s long composed of and occurs 3 times per orbit. After that update, the calibration sequences are much shorter (~0.6s) but occurs every 30 seconds. Moreover, due to more frequent calibration, the monitoring measurements are no longer needed to monitor the noise diode.

For measurements in the Intermonitoring mode (Obs mode), two kind of processing can be used according to the measured brightness temperature. If this temperature is smaller than the reference load inside the instrument, the NIR processing is used; if the temperature is greater, the DNB processing is used. The transition from one processing to the other will occur more or less close to the coast depending on the internal temperature of the MWR. The internal temperature of the MWR is such that
only a small percentage of measurements required a DNB processing in this cycle as shown by Figure 2 for S3A and S3B.

This figure shows also the passage over the US KREMS radar facility in the Kwajalein atoll (9°23’47” N - 167°28’50” E) in the Pacific. For safety reasons, the MWR is switched to a specific mode about 50 km before the facility location and back to nominal mode 50km after. Since the 17th January, the safing area is enlarged to 300km following event of 24th November.

*Figure 2 : Map of measurements with DNB processing for 36.5GHz channel (red) and safety mode for both channels over KREMS (blue) (S3A on top panel, S3B bottom panel)*
3.2 Calibration parameters

To monitor the instrument behavior during its lifetime, the relevant parameters of the MWR internal in-flight calibration procedure are presented in the following subsections. These parameters are:

- the gain: this parameter is estimated using the two types of Dicke Non-Balanced calibration measurements (100% and 50% of injection). The DNB processing of the Earth measurements uses this parameter.
- the noise injection temperature: this parameter is measured during the Noise Injection calibration measurements. The NIR processing of the Earth measurements uses this parameter.

Data used for the diagnosis presented here are data generated by PDGS at Svalbard core ground station.

3.2.1 Gain

3.2.1.1 Sentinel-3A

Figure 3 shows the monitoring of the receiver gain for cycle 39 of S3A. The mean value over the cycle is 4.77mV/K and 4.54mV/K for channel 23.8GHz and 36.5GHz respectively. These values are close to values estimated on-ground during characterization of the instrument (4.793mV/K and 4.665mV/K for channels 23.8GHz and 36.5GHz respectively).

For channel 23.8GHz, nominal behavior is observed since only 1 cycle of data is considered in this section. For channel 36.5GHz, the gain is still not stabilized after the stress due to the RFI of the 24th November.
3.2.1.2 Sentinel-3B

Figure 4 shows the monitoring of the receiver gain for cycle 20 of S3B. The mean value over the cycle is 4.5mv/K and 4.56mV/K for channel 23.8GHz and 36.5GHz respectively. These values are close to values estimated on-ground during characterization of the instrument (4.57mV/K and 4.56mV/K for channels 23.8GHz and 36.5GHz respectively).

For 23.8GHz channel, nominal behavior is observed since only 1 cycle of data is considered in this section. For 36.5GHz, a small slope during the first half of the cycle is observed.

Figure 4: S3B Monitoring of receiver gain for both channels: 23.8GHz (left) and 36.5GHz (right)

3.2.2 Noise Injection Temperature

3.2.2.1 Sentinel-3A

Figure 5 shows the monitoring of the noise injection temperature for cycle 39 of S3A. The noise injection temperature show no trend over the cycle for 23.8GHz channel. For 36.5GHz channel a small slope is observed along the cycle. The average value of the noise injection temperatures are 313.8K/288.4K for channels 23.8GHz/36.5GHz respectively.

For both channels, nominal behavior is observed since only 1 cycle of data is considered in this section.
3.2.2.2 Sentinel-3B

Figure 6 shows the monitoring of the noise injection temperature for cycle 20 of S3B. The noise injection temperature show no trend over the cycle for both channels. The average value of the noise injection temperartures are 309.8K/310.9K for channels 23.8GHz/36.5GHz respectively.

For both channels, nominal behavior is observed since only 1 cycle of data is considered in this section.

3.3 Brightness Temperatures

Data used for the diagnosis presented here are data generated at Land Surface Topography Mission Processing and Archiving Centre [LN3].

The two following figures show maps of brightness temperatures for the two channels of S3A split by ascending (right part) and descending (left part) passes. Figure 7 and Figure 8 concern the channels 23.8GHz and 36.5GHz respectively. These maps show a good contrast between ocean and land for both channels.
Figure 7: Map of S3A Brightness temperatures of channel 23.8GHz for ascending (right) and descending (left) passes

Figure 8: Map of S3A Brightness temperatures of 36.5GHz channel for ascending (right) and descending (left) passes

Figure 9 and Figure 10 concern the channels 23.8GHz and 36.5GHz respectively also split by ascending (right part) and descending (left part) passes. These maps show a good contrast between ocean and land for both channels.
From these pictures, we can see that S3A and S3B brightness temperatures seem to be close, but they do not provide an accurate number. Figure 11 shows histograms of MWR brightness temperatures over ocean for S3A and S3B for the period corresponding to the Cycle 42 of S3A. We can see how close the two instruments are after this update. It subsists a bias of only 0.4K for 23.8GHz and 0.2K for 36.5GHz as expected from the commissioning results.

### 3.4 Geophysical products monitoring

The inversion algorithms allow to retrieve the geophysical products from the measurements of the radiometer (brightness temperatures measured at two different frequencies) and the altimeter (backscattering coefficient ie sigma0). Four geophysical products are issued from the retrieval algorithms: the wet tropospheric correction, the atmospheric attenuation of the Sigma0, the water vapor content, the cloud liquid water content. This section provides an assessment of two of these retrievals used by the SRAL/MWR L2 processing: the wet tropospheric correction and the atmospheric attenuation of the Sigma0. The wet tropospheric correction is analysed through the MWR-ECMWF difference of this correction.
3.4.1 Wet Tropospheric Correction

Figure 12 presents the histograms of the MWR-ECMWF differences of wet tropospheric correction (ΔWTC) for cycle 27. In this figure, S3A/B corrections are compared to the correction retrieved by Jason-3 (IGDR) and SARAL (IGDR) over the same period.

The standard deviation of the difference MWR-ECMWF corrections for S3A and S3B is around 1.4cm for SAR and PLRM corrections respectively while it is around 1.5cm for SARAL and 1.2cm for Jason-3. First Jason-3 benefits from its three channels radiometer (18.7GHz, 23.8GHz, 34GHz), providing a correction with a smaller deviation with respect to the model. SARAL/MWR is closer to S3A/B in this context with its two channels (23.8GHz and 37GHz for SARAL, 23.8 and 36.5GHz for S3A/B). Then the standard deviation for SARAL is the closest reference, even though the Sigma0 in Ka band raises some questions. With the use of NTC products for S3A/B, the ΔWTC for the three instruments are directly comparable since all use ECMWF analyses for the computation of the model correction. The standard deviation of ΔWTC for S3A/B is smaller than for SARAL meaning that we have a better estimation of the correction for S3A according to these metrics. Jason-3 gives the best performances with the smallest deviation. Moreover, one can notice that S3A/B SAR and PLMR corrections have very similar performances as mean(std) of ΔWTC are close to:

- 0.08cm(1.35cm) and 0.09cm(1.34cm) for S3A SAR and PLRM respectively
- -0.12cm(1.41cm) and -0.1cm(1.40cm) for S3B SAR and PLRM respectively

S3A and S3B corrections present a small bias of 0.20cm for that period.

![Figure 12: Histograms of MWR-ECMWF difference of wet tropospheric correction for SARAL, Jason3, S3A and S3B (selection of latitude between -60°/60° for all instruments, distance to shoreline >50km for S3A). Left: Sentinel-3A/B SAR measurements; Right: Sentinel-3A/B PLRM measurements](image)

Figure 13 presents a map of the ΔWTC for cycle 39 of Sentinel-3A only for SAR correction on the left and PLRM correction on the right. Figure 14 concerns the Sentinel-3B ΔWTC for its cycle 20. For that period,
the maps show geographical patterns expected for this parameter. Note that the color scale is centered to the mean value. The comparison with Jason-3 map of ΔWTC (Figure 15) shows similarities although Sentinel-3A/B ΔWTC is larger than Jason3 because of their different instrument configuration.

**Figure 13**: S3A MWR-ECMWF difference of wet tropospheric correction for S3A cycle 39: using SAR (left) and PLRM altimeter backscatter (right)

**Figure 14**: S3B MWR-ECMWF difference of wet tropospheric correction for S3B cycle 20: using SAR (left) and PLRM altimeter backscatter (right)
Figure 15: Jason MWR-ECMWF difference of wet tropospheric correction (IGDR product)
3.4.2 Atmospheric Attenuation

The Figure 17 presents the histograms of the Ku band atmospheric attenuation of the Sigma0. In this figure, S3A and S3B attenuations are compared to the model attenuation computed from ECMWF analyses and Jason3 attenuation from IGDR products. The results for both instruments are very similar to model results with an average attenuation close to 0.21dB for S3A, 0.22dB for S3B, 0.20dB for Jason3 and 0.2dB for model attenuation. Note that the model attenuation shows in that histogram is the attenuation computed at S3A time and geolocation.

![Histograms of Ku band Atmospheric attenuation of the Sigma0 for S3A, S3B, Jason3, Model attenuation (selection of latitude between -60°/60° for all instruments, distance to shoreline >50km for S3A) for the period of S3A cycle 42](image1)

**Figure 16**: Histograms of Ku band Atmospheric attenuation of the Sigma0 for S3A, S3B, Jason3, Model attenuation (selection of latitude between -60°/60° for all instruments, distance to shoreline >50km for S3A) for the period of S3A cycle 42

Left: Sentinel-3A/B SAR measurements; Right: Sentinel-3A/B PLRM measurements

Figure 17 shows a map of the difference of MWR attenuation and model attenuation computed from ECMWF analyses for S3A (left panel) and S3B (right panel). Globally a bias of 0.01 dB between MWR and model attenuation can be estimated from this plot.

![Map of difference of MWR-model atmospheric attenuation for S3A (left) and S3B (right)](image2)

**Figure 17**: Map of difference of MWR-model atmospheric attenuation for S3A (left) and S3B (right)
4 Long-term monitoring

In this section, a long-term monitoring of the MWR behaviour is presented.

4.1 Internal Calibration parameters

This section presents a long-term monitoring of internal calibration parameters. Data used for the diagnosis presented here are:

- Reprocessed data (processing baseline 2.15) from cycle 1 to cycle 16
- MWR L1B data generated by PDGS at Svalbard core ground station are used from 26/10/2016

4.1.1 Gain

4.1.1.1 Sentinel-3A

Figure 18 shows the daily mean of the receiver gain for both channels. This calibration parameter is used in the DNB processing of the measurements. As seen previously in section 3.1, only a small part of the measurements are processed in DNB mode. The first part of the monitoring of the calibration parameters shown here is performed with products generated during the reprocessing using the processing baseline 2.15, the second part using NRT products from the day of the IPF update on the Svalbard ground station forward.

From the two panels of Figure 18, one can see that the receiver gain has a different evolution for each channel. The gain for the 23.8GHz channel has slowly increased since the beginning of the mission showing four slopes and three inflexion points at August 2016, February 2017 and June 2017. It seems to be almost stable since cycle 19 (July 2017). The gain has increased of +0.03mv/K since the beginning of the mission. For the 36.5GHz channel, the gain is increasing from cycle 1 and then starts to decrease at the beginning of cycle 4. During cycle 15, it started to increase again until cycle 18 and then starts a decrease. The gain has decreased of 0.03mV/K since the beginning of the mission. Due to the small number of data processed using this parameter, it will be difficult to assess if this decrease has an impact on data quality. The monitoring will be pursued and data checked for any impact.

The update of the calibration timeline of the 1st March 2018 has an impact on the standard deviation and minimum and maximum values of the gain (as explained in section 3.2.1), but there is no evidence of a change in the daily mean value.

A step of the gain of the 36.5GHz channel is seen during cycle 38. Investigations carried out have shown that the cause is a RFI around the KREMMS facility. The step observed during the cycle 41 for the gain of both channels is due to an update of the ground processor. The impact on the brightness temperatures is negligible and concerns only measurements over land for the 36.5GHz channel.
4.1.1.2 Sentinel-3B

Figure 19 shows the daily mean of the receiver gain for both channels. The monitoring of the calibration parameters shown here is performed with products generated operatively by the Land Processing center (LN3).

From the two panels of Figure 19, one can see that the receiver gain has a different evolution for each channel. The gain for the 23.8GHz channel has slowly increased since the beginning of the mission and seems stabilized since September 2018. The update of the MWR characterization file of the 6th December 2018 caused the change of value in the computed value of the gain observable at that date. For the 36.5GHz channel, the gain is decreasing since the beginning of the mission and seems stabilized since September 2018. A small step at the beginning of December is also observable, with the same cause than for the 23.8GHz channel (update of the characterization file).
4.1.2 Noise Injection temperature

4.1.2.1 Sentinel-3A

Figure 20 shows the daily mean of the noise injection temperature for both channels. This calibration parameter is used in the NIR processing of the measurements. As seen previously in section 3.1, the main part of the measurements are processed in NIR mode. Moreover the first part of the monitoring of the calibration parameters is performed using products generated during the reprocessing os processing baseline 2.15, the second part using NRT calibration products from the day of the IPF update on the ground station.

From the two panels of Figure 20, one can see that the noise injection parameter has a different evolution for each channel. For the 23.8GHz channel, the noise injection temperature has decreased of less than 0.5K during the first 2 cycles, after what there has been no significant change of behaviour until cycle 13. During this cycle, the noise injection temperature seems to start a slow decrease. For the channel 36.5GHz, one can see that the injection temperature is not stable: it seems to follow some kind of periodic signal combined with a trend. Since cycle 19, the gain is slowly decreasing as it has done from July 2016 to February 2017. The monitoring will be pursued and data checked for any impact.

The update of the calibration timeline of the 1st March 2018 has an impact on the standard deviation and minimum and maximum values of the gain (as explained in section 3.2.1), but there is no evidence of a change in the daily mean value.

Some peak values are noticeable at the end of cycle 4 (mainly channel 23.8GHz), at the end of cycle 6, during cycle 9, 10, 12 and 16. Some of these peaks concerns both channels at the same time, while a small part of them only one of them. The investigations performed in the cycle 6 report has shown that these measurements are localized around a band of latitude that may change along the time series. The source is not yet clearly identified but a intrusion of the Moon in the sky horn is suspected.

A step of ~0.2K is seen during cycle 38 as observed in section 3.2.2. Investigations carried out have shown that a RFI around the KREMMS facility caused a stress to the MWR.

![Figure 20: Sentinel3-A Daily statistics of the noise injection temperature for channel 23.8GHz (left) and 36.5GHz (right): mean (bold line), min/max (thin line), standard deviation (shade)]
4.1.2.2 Sentinel-3B

Figure 21 shows the daily mean of the S3B noise injection temperature for both channels. This calibration parameter is used in the NIR processing of the measurements. The monitoring of the calibration parameters shown here is performed with products generated operationally by the Land Processing center (LN3).

From the two panels of Figure 20, one can see that the noise injection parameter has a different evolution for each channel. For the 23.8GHz channel, the noise injection temperature has increased at the beginning of the mission and seems stabilized since September. For the channel 36.5GHz, one can see that the injection temperature is not stable: it seems to follow a trend. The two peaks observed in July are due to a maneuver for cold sky seeing (17 July) in preparation for Moon seeing maneuver (27 July).

A small step at the beginning of December is observable, due to the update of the MWR characterization file.

![Figure 21: Sentinel3-B Daily statistics of the noise injection temperature for channel 23.8GHz (left) and 36.5GHz (right): mean (bold line), min/max (thin line), standard deviation (shade)](image-url)
4.2 Vicarious calibration

The assessment of the brightness temperatures quality and stability is performed using vicarious calibrations. Two specific areas are selected. Sentinel-3A data used in this section are:

- Coldest ocean temperature analysis uses Level 2 data:
  - data from processing baseline 2.15 reprocessing from June 2016 to April 2017.
  - STC Marine data from December 2016 to December 2017
  - NTC Marine data since cycle 26

- Amazon forest analysis uses Level 1B data:
  - data from processing baseline 2.15 reprocessing from June 2016 to April 2017.
  - STC Land data from LN3 processing center
  - NTC Marine data since cycle 26

4.2.1 Coldest ocean temperatures

The first area is the ocean and more precisely the coldest temperature over ocean. Following the method proposed by Ruf [RD 1], updated by Eymar [RD 3] and implemented in [RD 7], the coldest ocean temperatures is computed by a statistic selection. Ruf has demonstrated how a statistical selection of the coldest BT over ocean allows detecting and monitoring drifts. It is also commonly used for long-term monitoring or cross-calibration [RD 4] [RD 5] [RD 6].

The Figure 22 presents the coldest ocean temperature computed following method previously described at 23.8GHz channel for Sentinel-3A/WMR and four other microwave radiometers: AltiKa/MWR, Jason2/Jason3/AMR and Metop-A/AMSU-A. For AMSU-A, the two pixels of smallest incidence (closest to nadir) are averaged. The Figure 23 presents the same results for the liquid water channel of the same four instruments: 36.5GHz for Sentinel-3A, 37GHz for AltiKa, 34GHz for Jason2/Jason3 and 31.4Ghz for Metop-A.

Concerning the 23.8GHz channel presented on Figure 12, one can see the impact of the calibration of the MWR with the increase of the coldest ocean brightness temperature: around 135K before and 140K after the update of the characterisation file and LTM files for the STC on the fly products (green line). The temperature of the coldest ocean points is now closer to the other sun-synchronous missions (Metop-A, SARAL/AltiKa). The light green line is for the reprocessed data of processing baseline 2.15 that is with the same configuration than the on-the-fly products after January. One can notice the very good agreement on the overlapping period.

The analysis for the liquid water channel (Figure 23) is more complicated due to the different frequency used by these instruments for this channel: 36.5GHz for S3A/B, 37GHz for AltiKa, 34GHz for Jason2/Jason3 and 31.4Ghz for AMSU-A. But the coldest temperature can be used relatively one with another. For instance, one can see that the difference between AltiKa and Jason-2/Jason3 is about 6K which is in line with the theoretical value estimated by Brown between the channel 34 GHz of JMR and the channel 37 GHz of TMR (-5.61 K ± 0.23 K) [RD 8]. Then we can expect that Sentinel3 should be closer
to AltiKa than Jason2 due to the measurement frequency. The STC and NTC products reprocessed using the new MWR characterisation file (light green curves) show hottest temperatures like AltiKa. For the on-the-fly NTC products, a jump in the temperatures occurs with the update of MWR characterisation file.

S3A is following the same behaviour than the other radiometers. Over the period of more than two years of its flight, no drift is noticed for S3A. For S3B, the period is too short to allow a drift analysis but it is reassuring to see that the MWR has the same behaviour than the other radiometers. At the beginning of the mission, a bias is observed between S3A and S3B although the curve follows the same evolution. After the update of the MWR characterization file the 6th December, S3B presents values consistent with S3A as expected. This update will have a significant impact only for the coldest brightness temperatures.

**Figure 22**: Coldest temperature over ocean at 23.8GHz for S3A/B, SARAL/AltiKa, Jason2, Jason3 and Metop-A/AMSU-A

**Figure 23**: Coldest temperature over ocean for the liquid water channel S3AB, SARAL/AltiKa, Jason2, Jason3 and Metop-A/AMSU-A
4.2.2 Amazon forest

The second area is the Amazon forest which is the natural body the closest to a black body for microwave radiometry. Thus it is commonly used to assess the calibration of microwave radiometers [RD 2][ RD 3]. The method proposed in these papers have been used as a baseline to propose a new method implemented in [RD 7]. In this new approach, a mask is derived from the evergreen forest class of GlobCover classification over Amazon. The average temperature is computed here over a period of one month for all missions.

The averaged temperature over the Amazon forest is shown on Figure 24 and Figure 25 for water vapor channel (23.8GHz) and liquid water channel respectively. These two figures show the very good consistency of S3A/B with the three other radiometers on the hottest temperatures: around 286K for the first channel, and 284K for the second channel. The mean value as well as the annual cycle is well respected. These results show the correct calibration for the hottest temperatures and the small impact of the MWR calibration for the hottest temperatures when comparing the reprocessed data using processing baseline 2.15 (light green line) and the on-the-fly products, here NTC L1B products.

S3A is following the same behaviour than the other radiometers. Over the period of more than two years of its flight, no drift is noticed for S3A. For S3B, as for the coldest ocean temperatures, the period is too short to allow a drift analysis. At the beginning of the mission, no bias is observed for the hottest temperatures. After the update of the MWR characterization file the 6th December, a small bias of 0.3K is introduce between S3B and S3A as expected from the commissioning phase results.

4.3 Geophysical products

4.3.1 Monitoring of geophysical products

In this section, comparisons of MWR-model fields are performed for several instruments. The selected instruments are Jason2/Jason3/AMR and SARAL/AltiKa. For a long-term monitoring perspective, GDR products are used to compute the difference with respect to model values. Model values for each field are computed using ECMWF analyses data. GDR products for each mission have their own latency due to cycle curation and mission constraints such as the cold-sky calibration for Jason-2 and Jason-3 missions. Indeed, AltiKa GDR is available with delay of 35 days, while for Jason2 or Jason3 this delay is up to 60 days.

4.3.1.1 Wet tropospheric correction

Figure 26 shows the monitoring of the MWR-model differences of wet tropospheric correction ($\Delta$WTC) using Level2 STC products from the Marine Center. S3A/B corrections are compared to Jason2, Jason3 and SARAL corrections. For SARAL (annotated AL in Figure 26), Jason2 (J2) and Jason3 (J3), GDR products were selected. A 30-days moving window averaging is applied in order to smooth the day-to-day variations. The daily data is shown by the points, and the averaging shown by the line, both with the same color corresponding to each mission.

The daily average of $\Delta$WTC for S3A is close to 0cm since 10th of January up to 0.2cm since October 2017 while it is around 0.6cm for SARAL and Jason-2. S3B $\Delta$WTC daily average was around 0.7cm from May to November, close to AltiKa and J3 values. In December, the update of the characterization file in December 2018 modified the average to -0.1cm. This difference is small and results partial from the inversion algorithm. The more relevant parameter to assess the performance of a correction is the standard deviation of $\Delta$WTC. First Jason-2 and Jason-3 benefit from their three channels radiometer (18.7GHz, 23.8GHz, 34GHz), providing a correction with a smaller deviation with respect to the model. SARAL/MWR is closer to S3A/B/MWR in this context with its two channels (23.8GHz, 37GHz). Then the standard deviation for SARAL is the closest reference, even though the Sigma0 in Ka band raises some questions. With the use of NTC products for S3A/B, the $\Delta$WTC for the three instruments are directly comparable since all missions use ECMWF analyses for the computation of the model correction. The standard deviation of $\Delta$WTC for S3A/B is smaller than for SARAL meaning that we have a better estimation of the correction for S3A/B according to these metrics. Jason-2 and Jason-3 give the best performances with the smallest deviation. Moreover, one can notice that both SAR and PLMR corrections have very similar performances.
4.3.1.2 Atmospheric attenuation

Figure 27 shows the monitoring of the MWR-model differences of atmospheric attenuation ($\Delta\text{ATM}_\text{ATT}$) using Level2 STC products from the Marine Center. Sentinel-3A correction in Ku band is compared to Jason2/AMR and Jason3/AMR. SARAL/AltiKa is not shown here because the altimeter uses the Ka band. A 30-days moving window averaging is applied in order to smooth the day-to-day variations. The daily data is shown by the points, and the averaging shown by the line, both with the same color corresponding to each mission.

Figure 27 shows that the several evolutions affected mainly the average value of $\Delta\text{ATM}_\text{ATT}$: the daily average show steps when the configuration of the IPF is updated, while the standard deviation remains stable over the period. The mean of $\Delta\text{ATM}_\text{ATT}$ for Jason2 and Jason3 is 0.004dB and 0.003dB respectively, a little larger for S-3A with 0.014dB. The evolution is stable for Jason2/3, some jumps are observable for Sentinel-3A. The steps at the beginning of the period are due to processing configuration changes (MWR characterisation file, Long Term Monitoring file). During cycle 25, a step is observed over the mean and standard deviation of the difference. This step corresponds to the IPF update correcting the coding of the atmospheric attenuation in the product. The atmospheric attenuation can now have higher values in case of strong attenuation events. These points have an impact on the mean and the standard deviation because they have very high values with respect to the average attenuation in Ku band. A finer tuning of the retrieval algorithm is expected to correct for that. For S3B, a small bias is observed on the daily average with respect to S3A at the beginning of the mission. This bias seems closer to zero after the IPF update of the 6th December 2018 (S3B MWR characterisation file and SRAL configuration file). Standard deviation is similar for S3A and S3B.
Figure 27: Monitoring of difference MWR-model atmospheric attenuation: daily average (left) and standard deviation (right). Selection of points with latitude between -60° and 60°

4.3.1.3 Water vapor content

Figure 28 shows the monitoring of the MWR-model differences of atmospheric attenuation (ΔWV) using Level2 ShortTimeCritical (STC) and Non Time Critical (NTC) products from the Marine Center. Sentinel-3A correction is compared to Jason2/AMR and Jason3/AMR. A 30-days moving window averaging is applied in order to smooth the day-to-day variations. The daily data is shown by the points, and the averaging shown by the line, both with the same color corresponding to each mission.

Figure 28 shows that the several evolutions affected mainly the average value of ΔWV: the daily average show steps when the configuration of the IPF is updated, while the standard deviation is stable over the whole period. The mean of ΔWV for Jason2 is around -0.75kg/m², very close to AltiKa results of -0.58kg/m², around -1.06kg/m² for Jason3, and a little larger for Sentinel-3A: around 0.25kg/m² in average. The standard deviation of ΔWV is very similar between AltiKa (2.50kg/m²), S3A (2.25kg/m² for PLRM) and S3B (2.31kg/m² for PLRM), and a little smaller for Jason2 and Jason3 around 2kg/m². A finer tuning of the retrieval algorithm is expected to correct for the small difference of the daily average. For S3B, a bias of about 1kg/m² is observed on the daily average with respect to S3A at the beginning of the mission. This bias is reduced to 0.2kg/m² after the IPF update of the 6th December 2018 (S3B MWR characterisation file and SRAL configuration file). Standard deviation is similar for S3A and S3B.
4.3.1.4 Cloud liquid water content

Figure 29 shows the monitoring of the MWR-model differences of cloud liquid water content ($\Delta WC$) using Level2 STC products from the Marine Center. Sentinel-3A/B fields is compared to Jason2/AMR, Jason3/AMR and SARAL/AltiKa. A 30-days moving window averaging is applied in order to smooth the day-to-day variations. The daily data is shown by the points, and the averaging shown by the line, both with the same color corresponding to each mission.

Figure 29 shows that the several evolutions affected mainly the average value of $\Delta WC$: the daily average show steps when the configuration of the IPF is updated but with a smaller effect than for the other geophysical parameters, while the standard deviation is stable over the whole period. The mean of $\Delta WC$ is close to 0.04 kg/m² for AltiKa, Jason2 and S3A/B but around 0.03 kg/m² for Jason3. The standard deviation of Sentinel-3A is little higher than for the three other missions: ~ 0.3 kg/m² for S3-A, ~ 0.2 kg/m² for the other missions. This point needs to be analyzed. For S3B, daily average is very close to S3A results since the beginning of the mission. The IPF update of the 6th December for S3B (MWR characterisation file and SRAL configuration file) had no significant impact on this parameter. Standard deviation is similar for S3A and S3B.
4.3.2 Comparison to in-situ measurements

4.3.2.1 Comparison to radiosonde observations

The database is under construction and validation. Studies are on-going.

Several networks exist as provider of radiosonde data. For time being, we are using radiosonde observations provided by IGRA network (Integrated Global Radiosonde Archive). This archive [http://www.ncdc.noaa.gov/oa/climate/igra/] gathers around 1500 stations from 1963 up to now. A quality control is applied on each station but there is no bias correction of the raw measurements.

This network provides measurements for open ocean islands, coastal and land stations. On this study, we applied the method proposed by S. Brown during the JMR on-orbit calibration (S. Brown, C. Ruf, S. Keihm, and A. Kitiyakara, “Jason Microwave Radiometer Performance and On-Orbit Calibration,” Mar. Geod., vol. 27, no. February 2015, pp. 199–220, 2004.). The first step is to select a subset of open ocean stations. Over this batch of open ocean station, we will work with stations close enough in space and time of S3A track (500km;9h) and a number of coincident measurements sufficient for the analysis. Figure 30 shows the coverage of all stations (blue and red points), red points are the stations selected for the analysis of S3A data.

The wet tropospheric correction derived from profile’s humidity and temperature measurements are compared to the MWR correction at the closest approach point with no land contamination. To avoid land contamination, a minimum distance from shoreline of 25km is required.

![Figure 30](image-url)

*Figure 30: IGRA archive coverage (blue+red). Red points are the stations selected for comparison to S3A wet tropospheric correction.*

First results of the comparison are provided in Table 3 for various spatial and temporal separation These preliminary results, the mean bias is 1cm and standard deviation of 2.64cm for all weather conditions with 315km and 6h as the bounds for the closest approach point. The std difference decreases as the closest approach bounds are reduced.

*Table 3: Mean and Std of the MWR-RaOb WTC differences*

Timeseries of the comparison of path delays from MWR and RaOb from selected stations is shown in Figure 31. The same bias and standard deviation than in Table 3. In that plot, is shown all data collocated within the following selection criteria: dist≤315km and dT≤6h. A small drift seems to be noticeable in that plot. It is too early to conclude on that “drift”. More analysis and editing are required on the RaOb data.

*Figure 31: Timeseries of MWR-RaOb path delay for selected stations from IGRA network (selection criteria: dist≤315km and dT≤6h)*
4.3.2.2 Comparison to GPS observations

For the comparison to GPS measurements, we started by using the Suominet database (https://www.suominet.ucar.edu). The project is a university-based GPS network developed for atmospheric research presented in this paper:

The network exploits the ability of ground-based GPS receivers to perform hourly measurements of the lower and upper atmospheres. Estimations of the wet and dry path delay can be performed from these GPS measurements. Measurements are provided every half-hour.

The number of stations is not constant over the period as shown in Figure 32. At the beginning of 2016, there was up to more than 120 stations providing data. While the latest files provide up to 99 stations per day. Moreover, all the stations provided in one file don’t give the estimation of the wet delay. No data are available after August 2018.

![Number of GPS station (2016-2018)](image)

Figure 32: Number of GPS stations in Suominet network (all stations in red, stations providing valid wet delay in blue)

For this analysis, a selection of stations is performed with the following criteria:

- Providing data along the full period 2016-2018
- Providing valid value of the wet delay
- Close to S3A ground track
Position of the station far from ice: some stations can be rounded by ice seasonally, thus MWR will be contaminated and the retrieved wet tropospheric correction will not be accurate.

Using the criteria mentioned above, we selected 19 stations indicated by the red points in Figure 33. Green curve of Figure 32 shows the effective number of station per day.

![Map of stations of Suominet network: all (blue), selected for comparison to S3 MWR (red)](image)

*Figure 33: Map of stations of Suominet network: all (blue), selected for comparison to S3 MWR (red)*

The selection in space is the same than for the radiosonde. The selection in time is easier in the context of the comparison with GPS as it provides measurements every 30 minutes. It means that if the ground track of S3A or S3B is close to a GPS station, the minimum time difference between MWR and GPS will be 30 minutes at maximum. To avoid land contamination, a minimum distance from shoreline of 25km is required.

Statistics of the comparison of MWR-GPS wet path delay are shown in Table 4. We observe a mean bias of 0.44 cm in the MWR-GPS wet path delay with a standard deviation of 2.86 cm, both are smaller than in the comparison of MWR to RaOb. The number of points which is greater in that context can explain a part of it.

*Table 4: Mean and Std of the MWR-GPS WTC differences*
Figure 34 show the timeseries of MWR-GPS wet path delay. As one can see, there is dates with no comparison. It is more likely to be due to missing measurements in the GPS database. This must be confirmed. The mean bias of 0.44cm is retrieved from Table 4 as well as the standard deviation of 2.86cm. A gap is observable from Mars 2017 to May 2017, due to an issue in the ingestion of the GPS data in our database. This will be corrected. There is also less data for the early 2018 period due to the diminution of valid station in the GPS dataset. A drift is not noticeable, at least not as clear as for the RaOb comparison.
