# What is desertification?

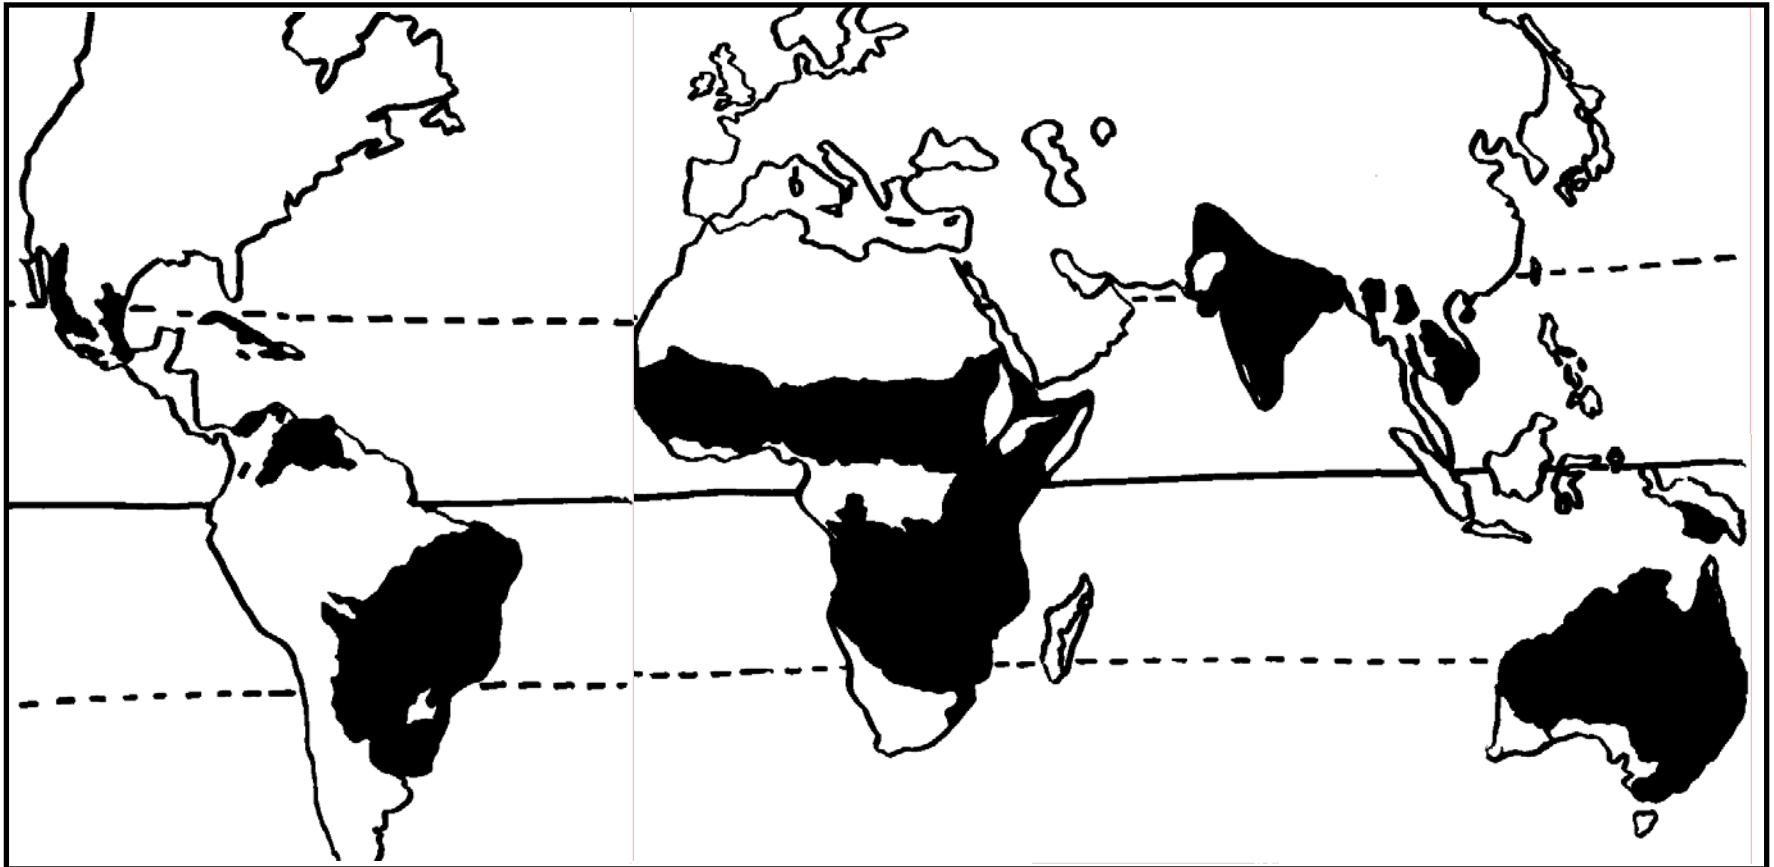

Desertification is degradation in dry lands

United Nations Convention on Combatting Desertification

# Global distribution of savannas

(basically the same as the summer-rainfall drylands)

# Savannas are mixed tree-grass systems

# Some facts about savannas

- World's largest land biome (~12%)
- Second largest Net Primary Productivity and carbon store ( $16.8 \times 10^{15}$  gC/y)
- Large 'natural' impact on atmosphere through fire, carbon cycle and dust
- Home to ~1 billion people; source of food and energy to most of them
- Centre of biodiversity (7000 species in Africa alone)

# Desertification sucks!

The single environmental issue affecting the livelihoods of the largest number of people worldwide

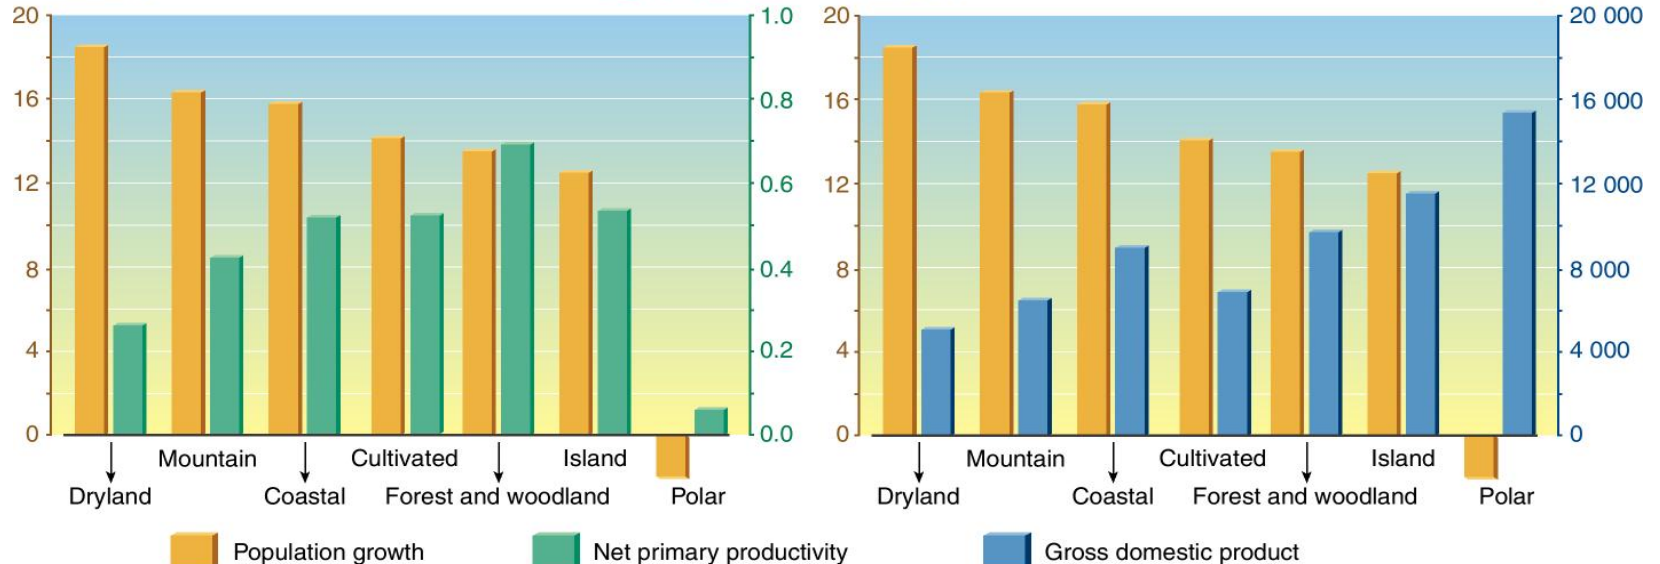

41% of Earth's land surface  
2 billion inhabitants  
90% in developing countries

Population growth between 1990 and 2000 in percentage

Net primary productivity kg / sq. meter / year

Population growth between 1990 and 2000 in percentage

Gross domestic product dollars per capita

Sources: Millennium Ecosystem Assessment

# What is degradation?

Does not spontaneously return to historical average within a *reasonable time* when you reduce the cause of change

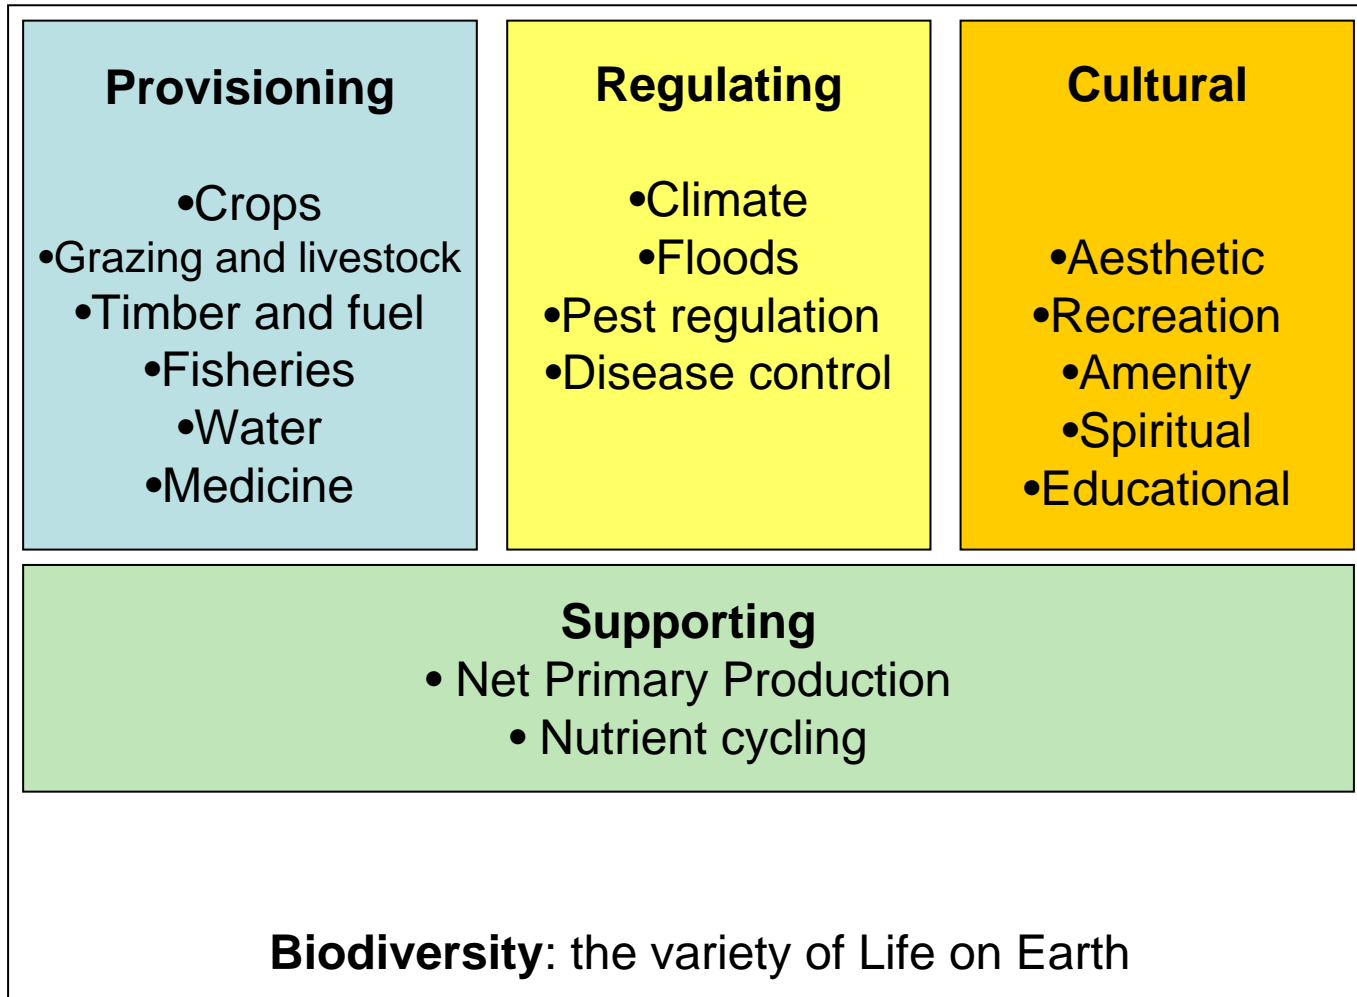

Degradation is a *persistent decrease* in the capacity of an ecosystem to deliver *ecosystem services*

The benefits that people get from ecosystems

-Millennium Ecosystem Assessment

# Ecosystem Services

## Millennium Ecosystem Assessment Classification

# Summary so far...

To detect desertification, we are looking for  
*a change in state* in savanna ecosystems

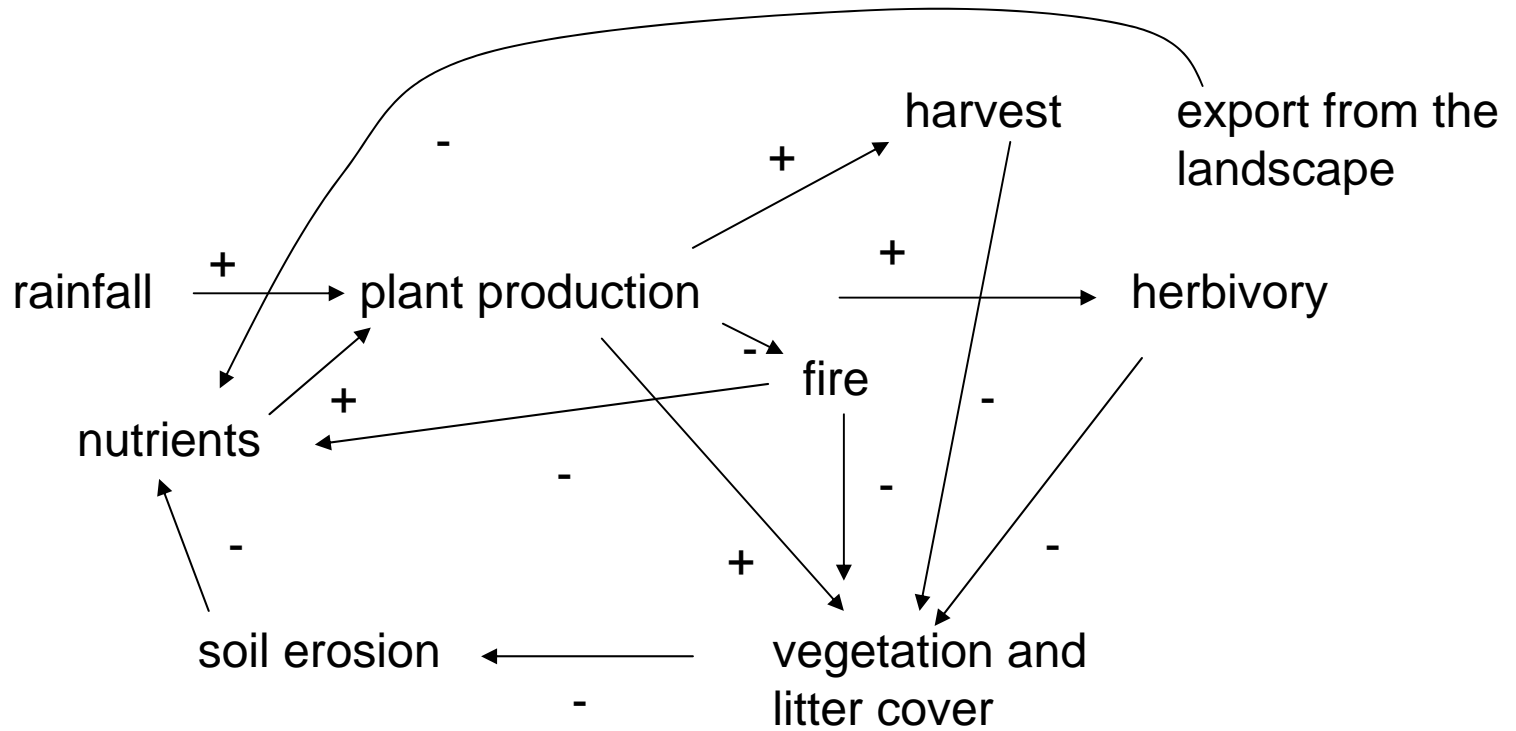

# Ecohydrological state change

(typically on silty soils)

# Nutrient state change

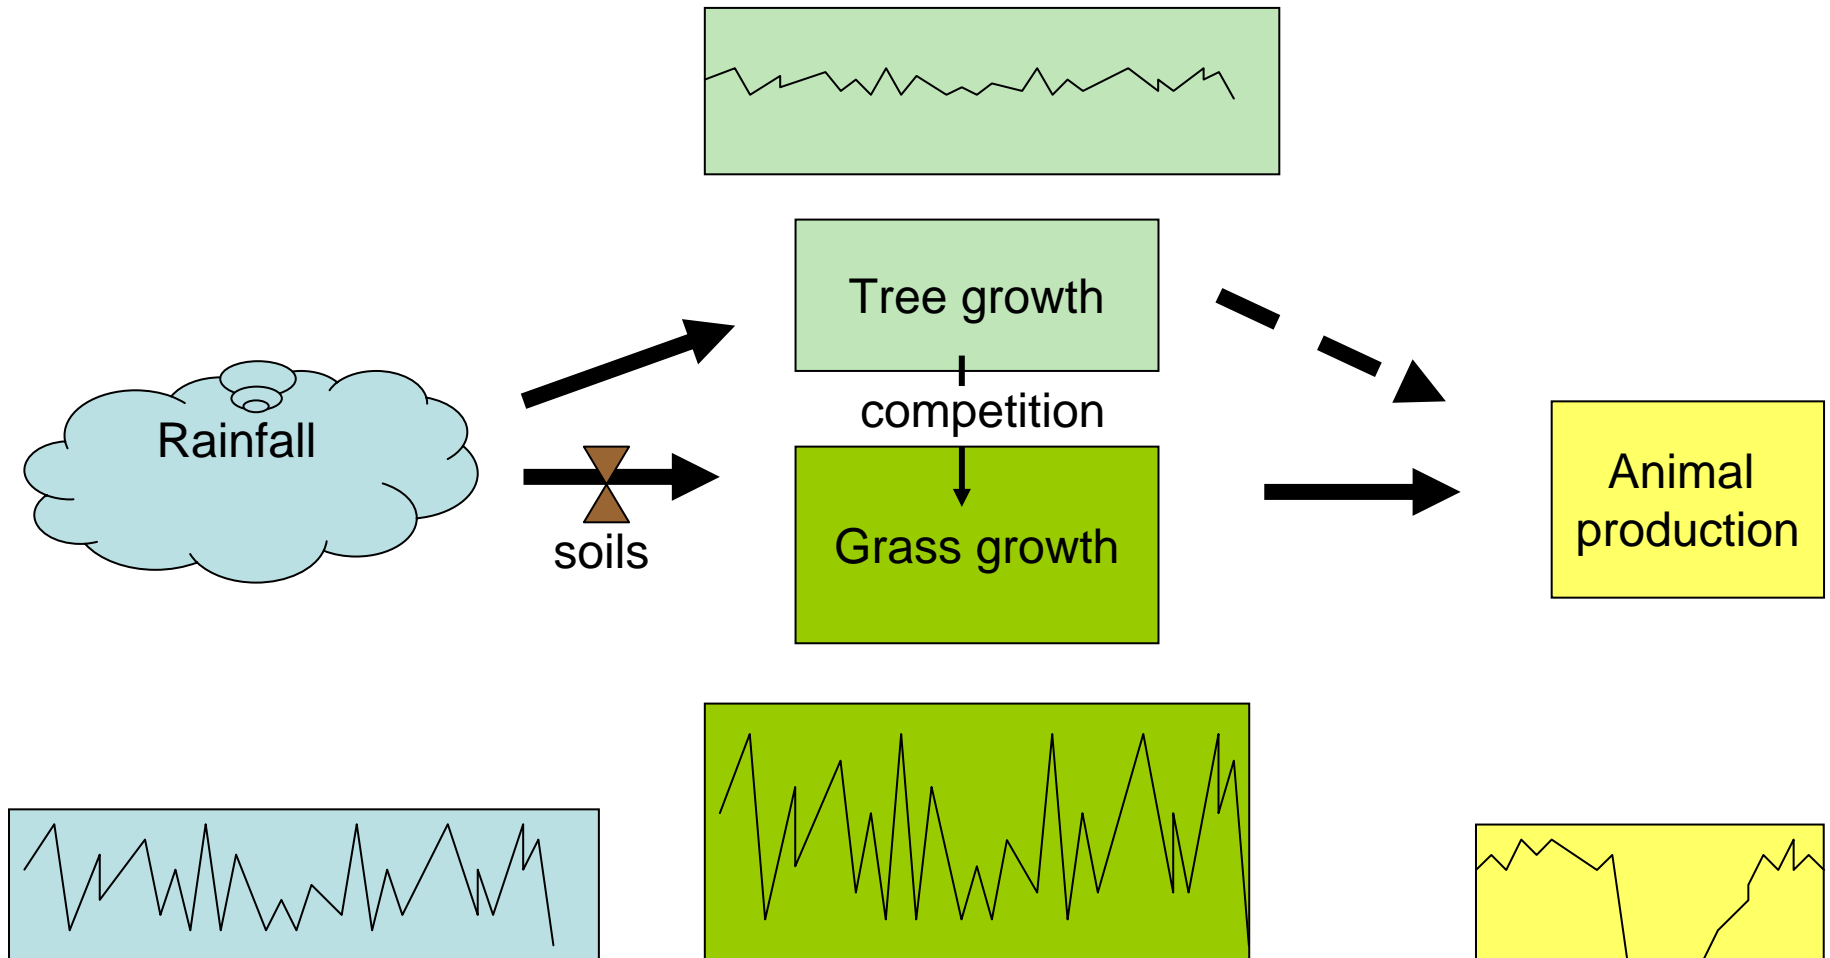

(typically on less-fertile, erodible soils eg sandy loams or loess)

# Change in the rain use efficiency

# Production in water-limited pastoral systems

# An electrical analog

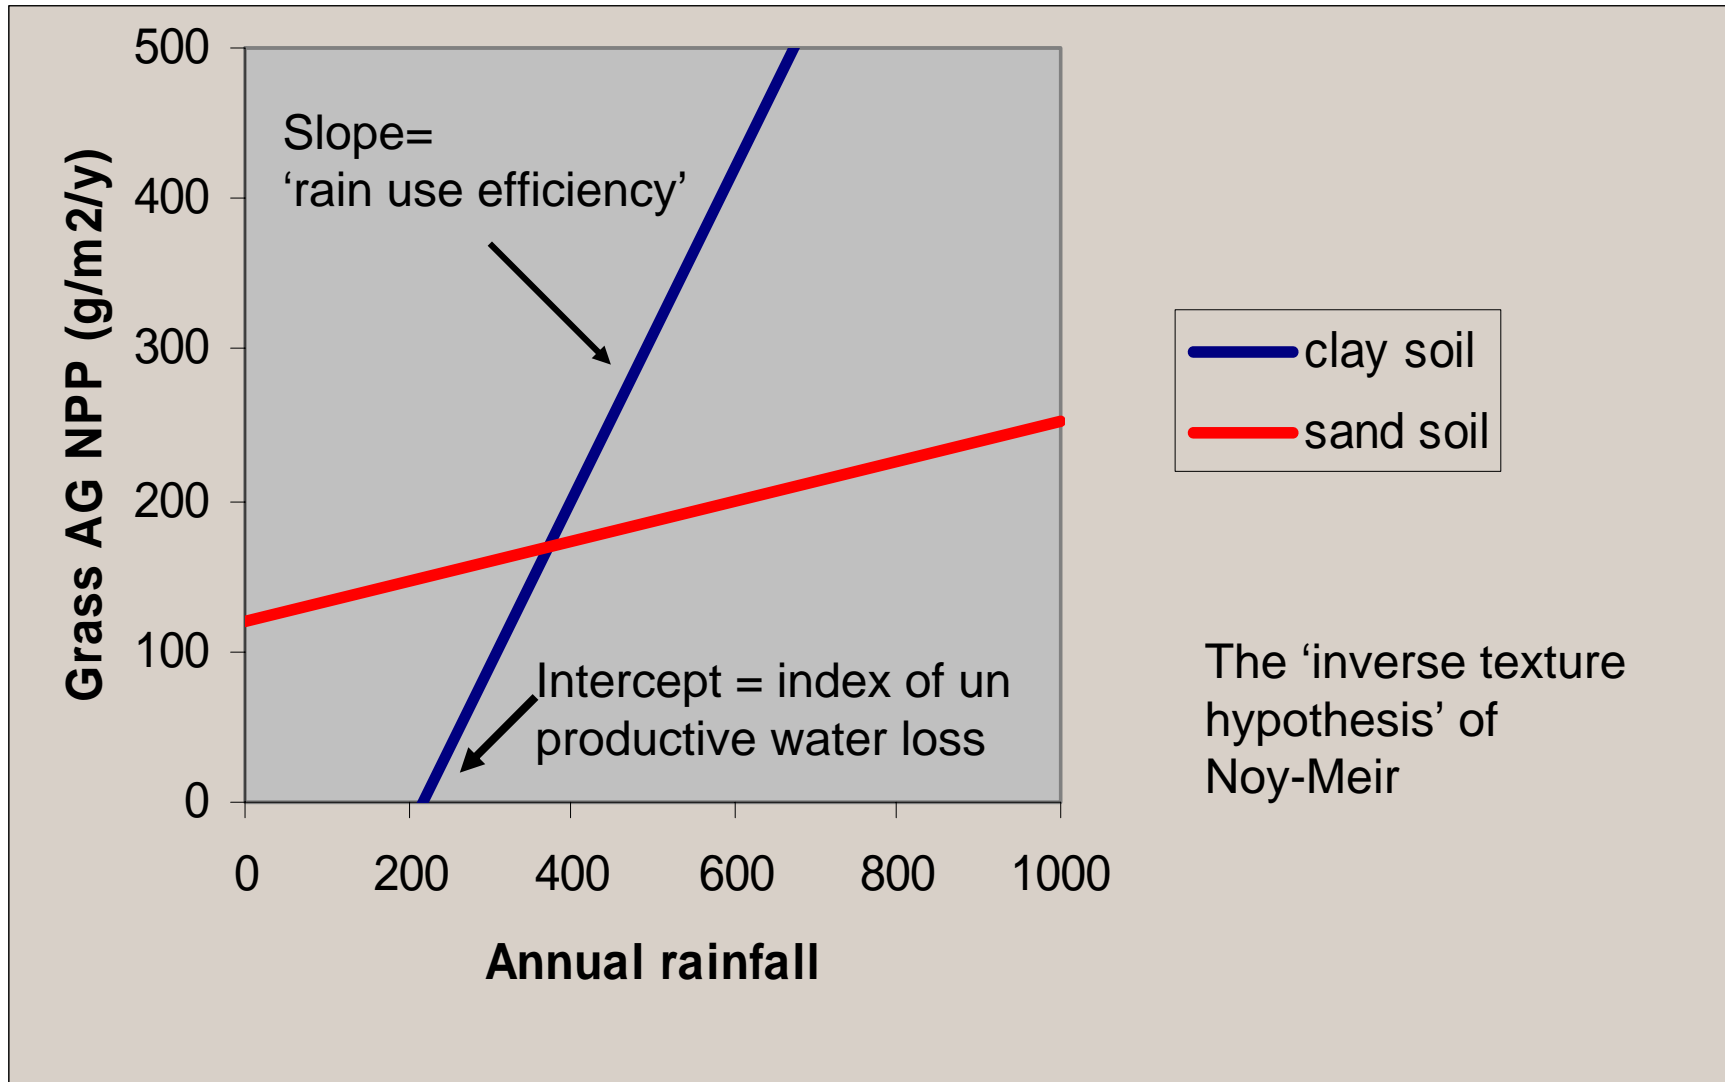

What controls the brightness of the lamp?

In pulsed systems, water availability controls the duration of growth opportunity

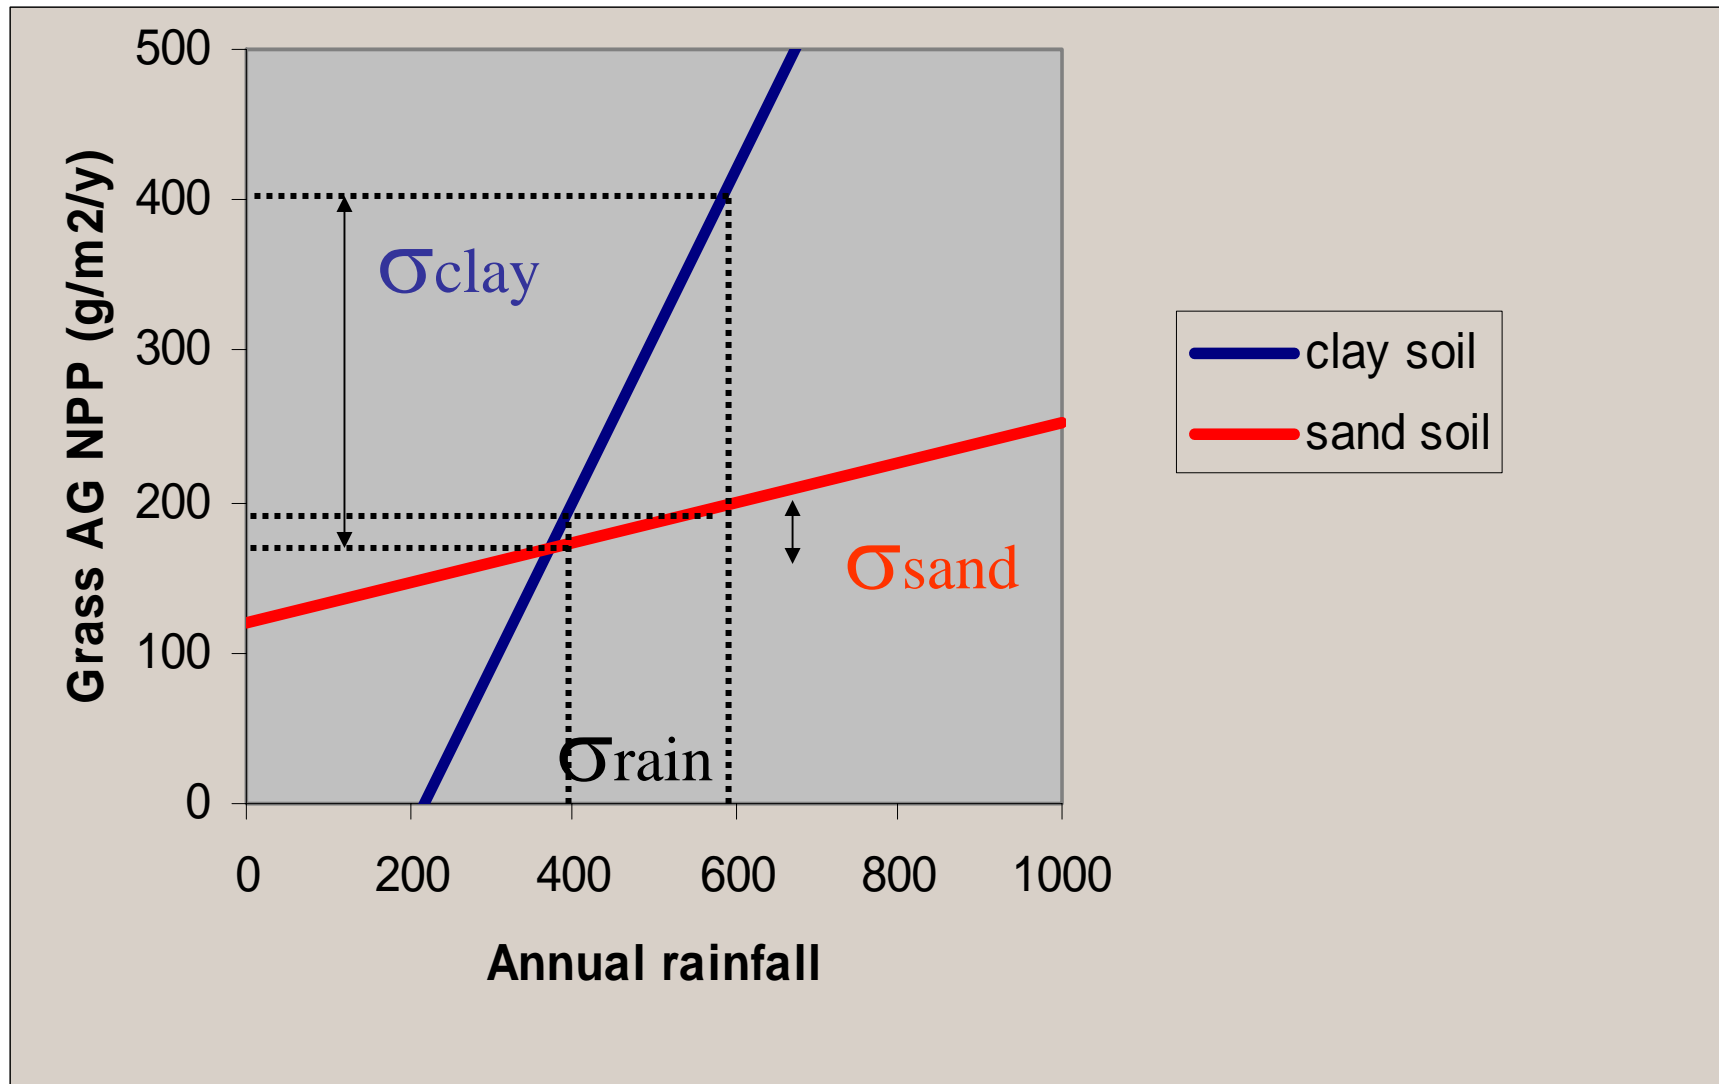

# Linear relation between grass production and rainfall

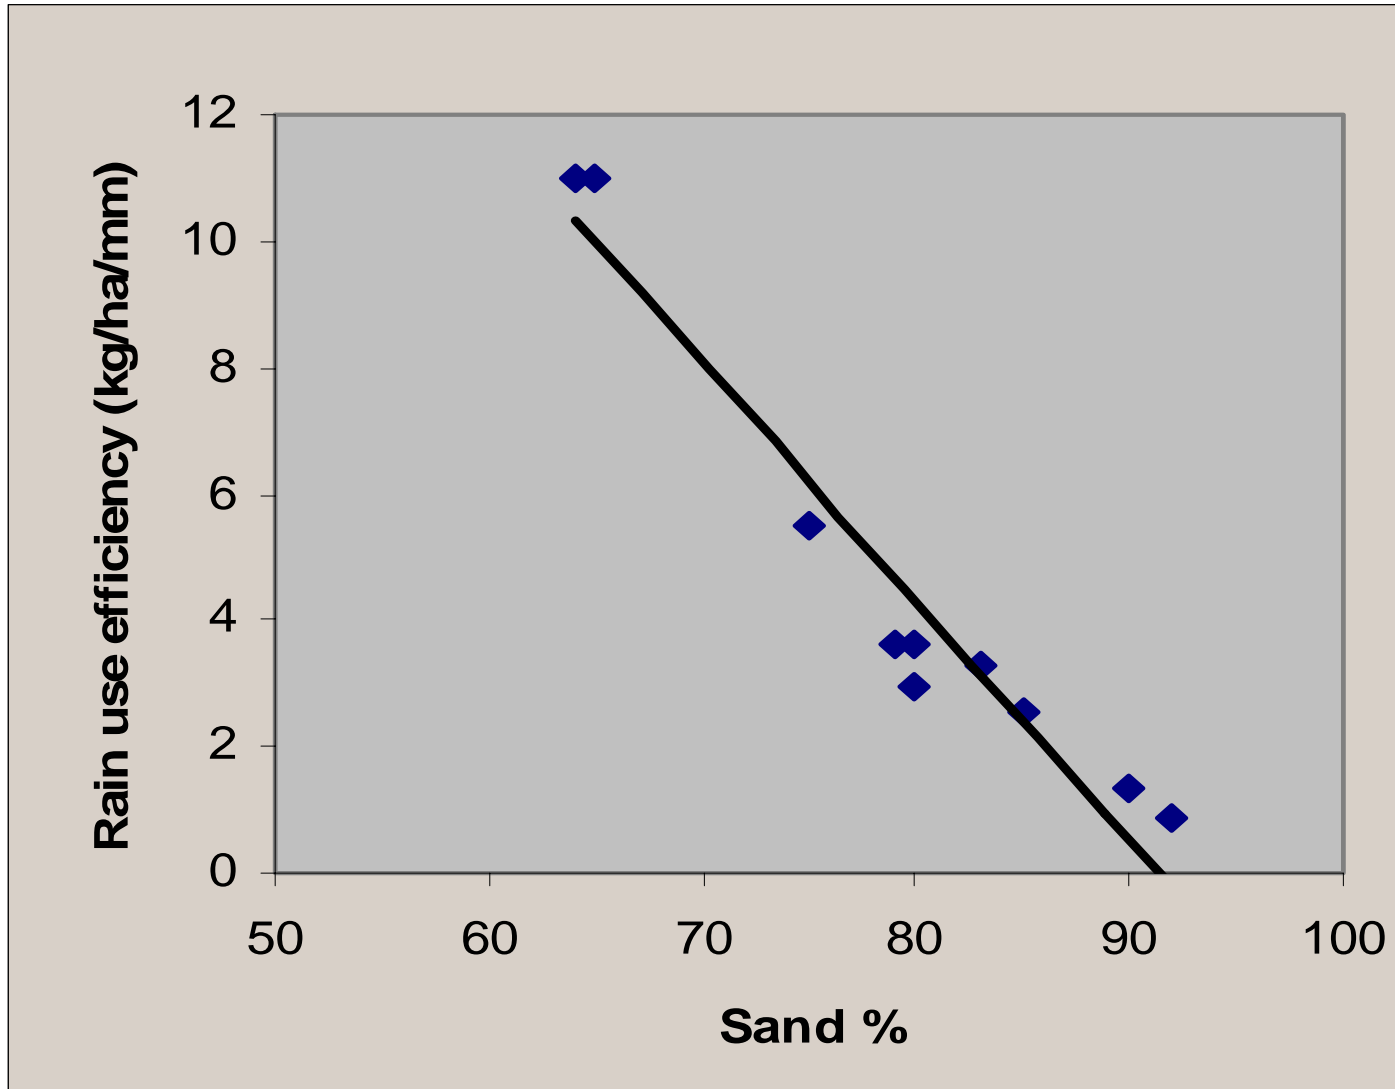

# Interannual variability of grass production is higher on clays than sandy soils

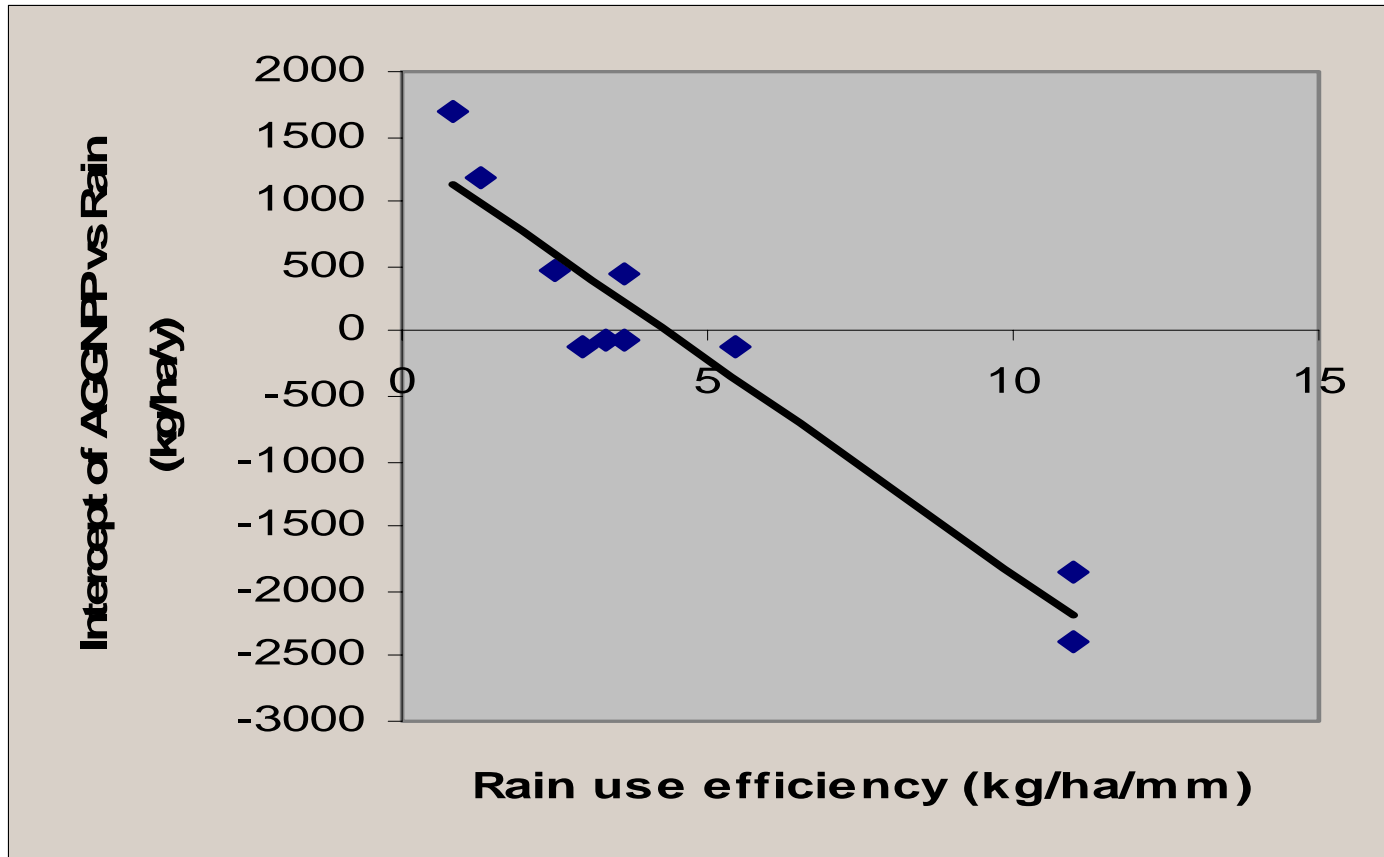

# Rain Use Efficiency

(g/m<sup>2</sup>/mm)

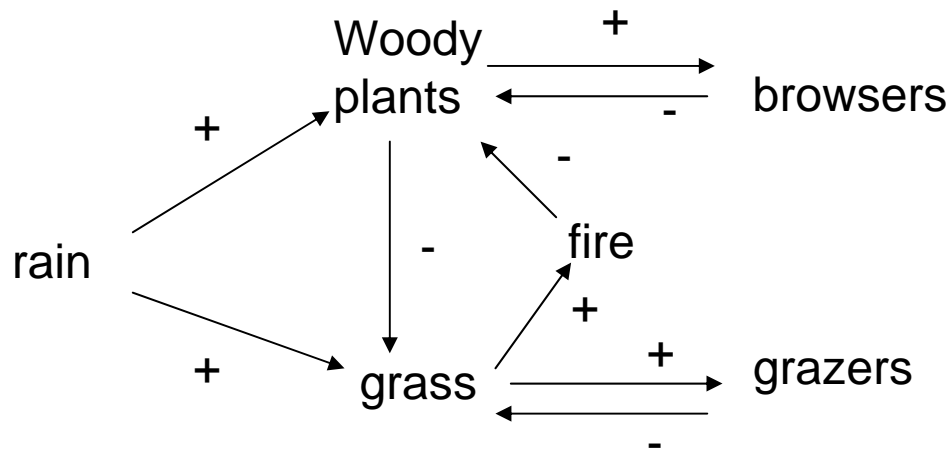

# Intercept

dependent on soil water holding capacity

# Changes in vegetation composition

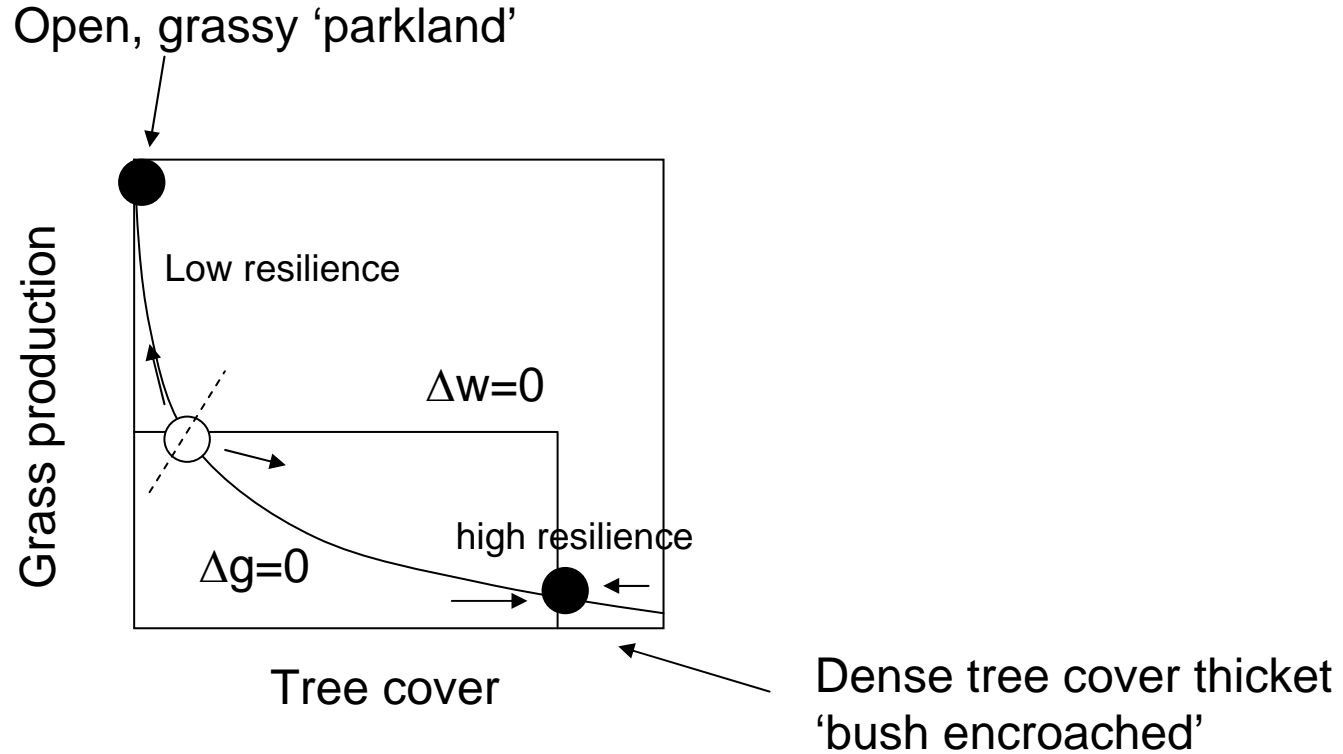

(to species less productive or less useful)

# Tree mass has a non-linear inverse effect on grass production

# Graphical stability analysis

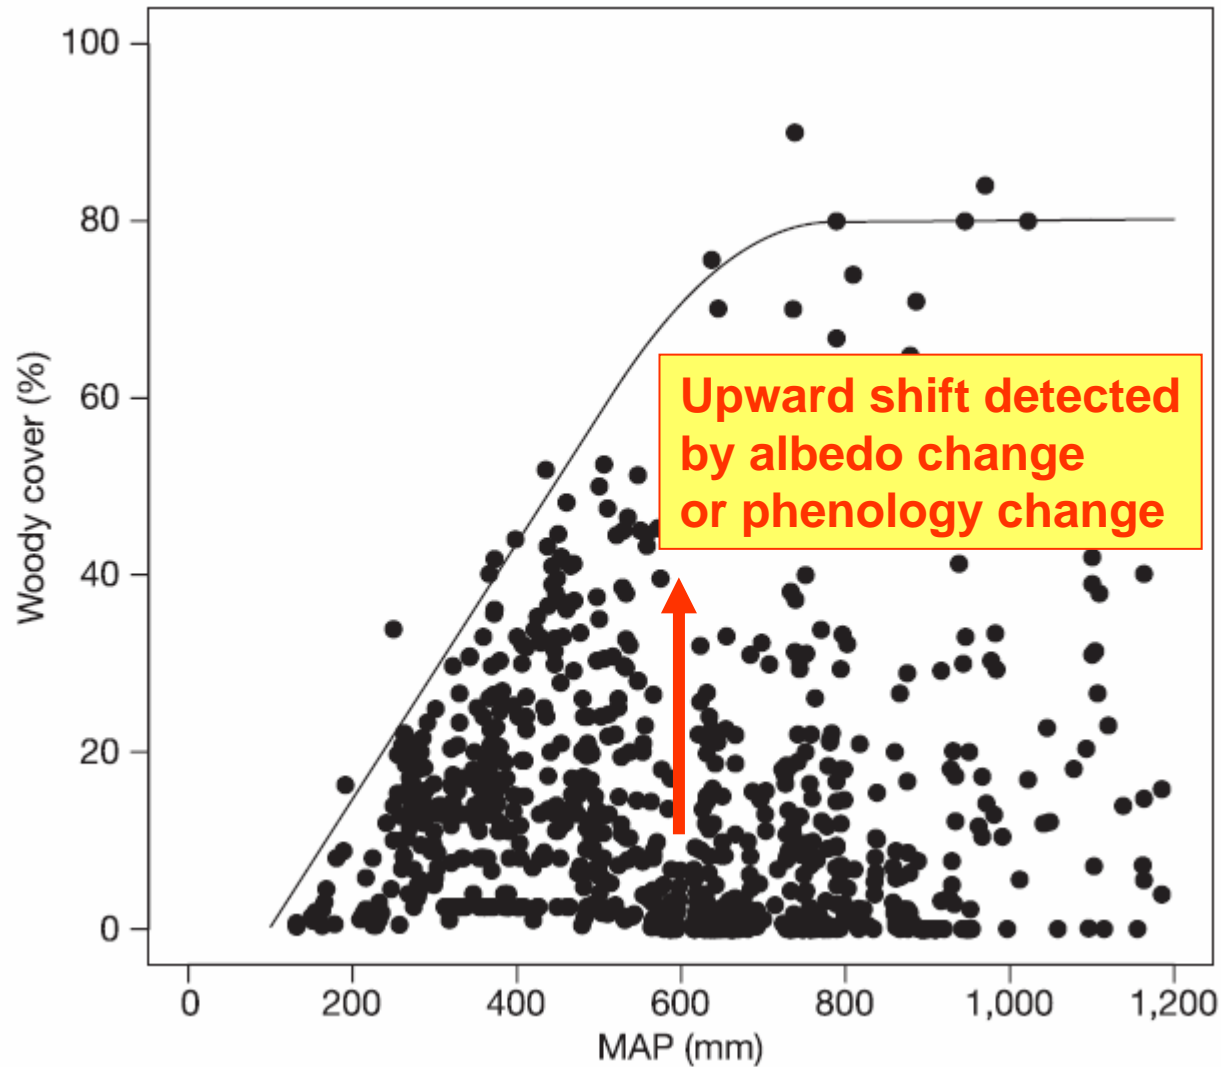

Scholes RJ 2003 Convex relationships in ecosystems containing trees and grass.  
*Environment and Resource Economics* 26, 559-574

# The actual tree-grass interaction is much more complex

# Relation between rainfall and quantity of trees in savannas

Sankaran et al 2005 Determinants of woody cover in African savannas *Nature* 438, 846-9

greenness  
indices

# 'Greenness' Vegetation Indices

eg NDVI= (Red-NIR)/(Red+NIR)  
and many others (SI, SAVI, EVI etc)

# Leaf Area Index

- The one-sided leaf area per unit of ground area
- Can go down to near 0 in the dry season
- Theoretical limit about 6

$$I = I_0 e^{-K \cdot LAI} \text{ (Beer's Law)}$$

therefore for LAI=6, k=0.5: I=5% of I<sub>0</sub>

- Hard to measure in forests due to saturation above ~ 3
- Seldom above 3 in drylands
  - Typically ~1 in savannas
- Useful for estimating evaporation and interception, but FPAR has fewer assumptions for modelling productivity

# FAPAR

Fraction of Absorbed Photosynthetically-Active Radiation intercepted by the vegetation canopy (range 0-1)

$$GPP = \varepsilon \sum (PAR * FPAR) * f(\text{stress, nutrients})$$

$$NPP = GPP - R_a$$

GPP = Gross Primary productivity (g/m<sup>2</sup>) (dry matter = 42% C)

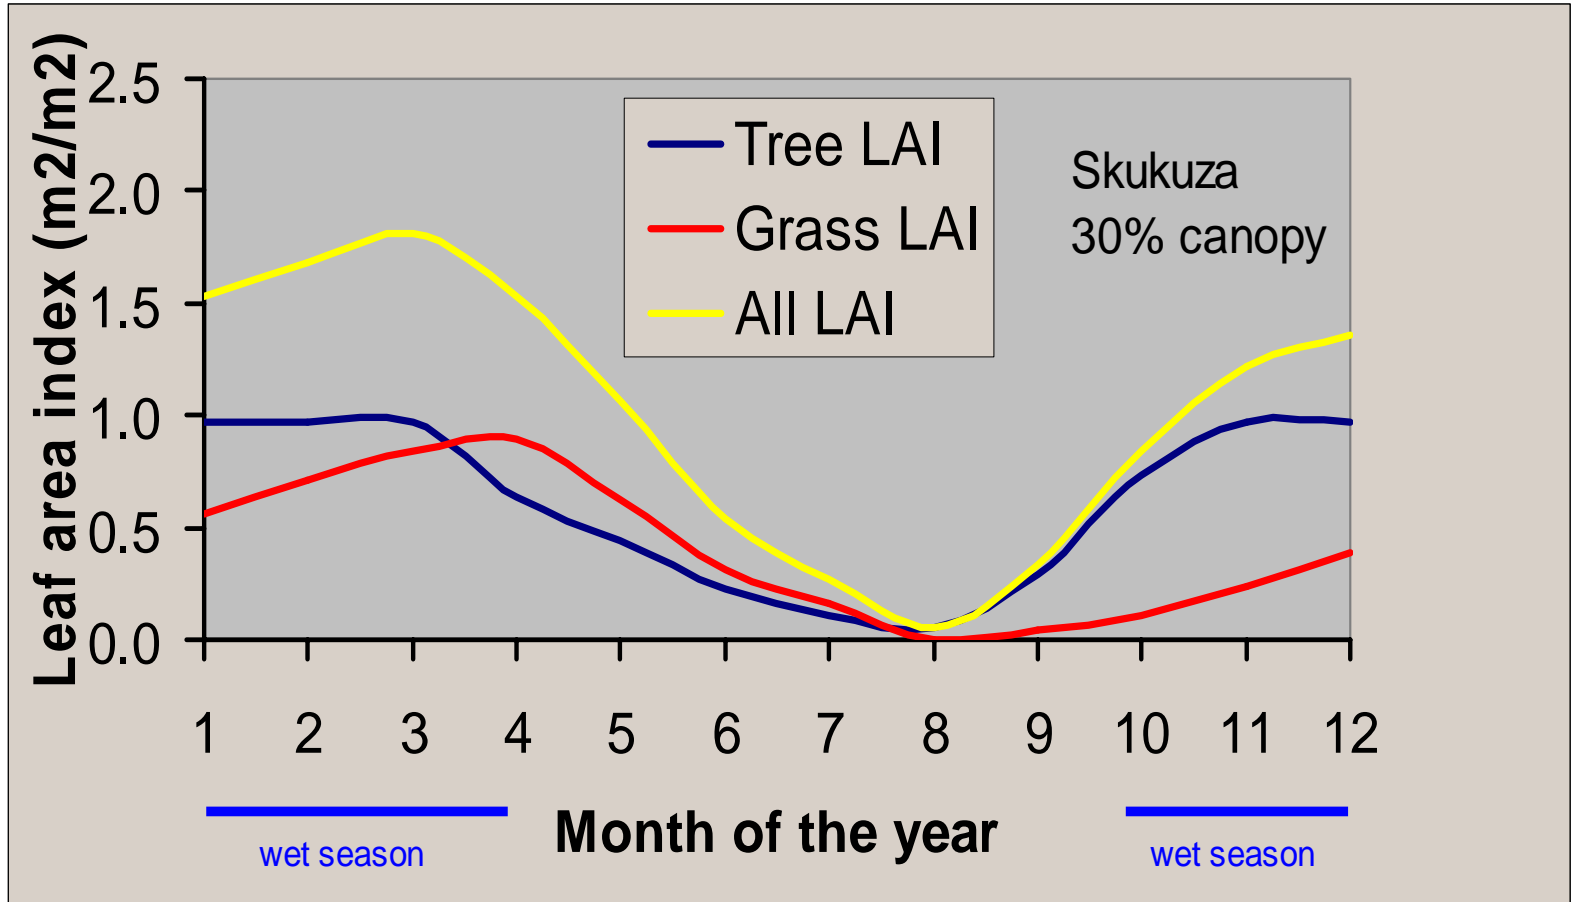

$\varepsilon$  = Radiation use efficiency (gC/MJ),  
species dependent (0.3-0.8 gC/MJ)

NPP = Net Primary Productivity (g/m<sup>2</sup>)

PAR = Photosynthetically-active radiation (400-700 nm) (W/m<sup>2</sup>)

$R_a$  = respiration by plants (~50% of GPP)

# Seasonal pattern of LAI

# Unscrambling the tree and grass signals

2001

2002

# Conclusions

- It is possible to define desertification in a rigorous and operational way, via the concept of persistent loss of ecosystem services
- There are mechanisms by which state change in ecosystem service delivery can occur: desertification is a real and widespread phenomenon
- These should be detectable using remote sensing, but require additional non-remote sensing data (soil and rainfall), time series, and often the unmixing of the tree and grass signal
