**Observed Doppler velocities = underlying current + background sea state** + sea state perturbations by surface current.

**First order** : only underlying current + background sea state

Hypothesis based on Doppler observation compared to HF radar except in area where tidal current is fast changing due to interaction with bathymetry :

**Second order** : sea state perturbed by surface current. Advanced models such as Doprim are needed to take into account modification of wave spectrum by surface current gradients.

## CDOP geophysical model function

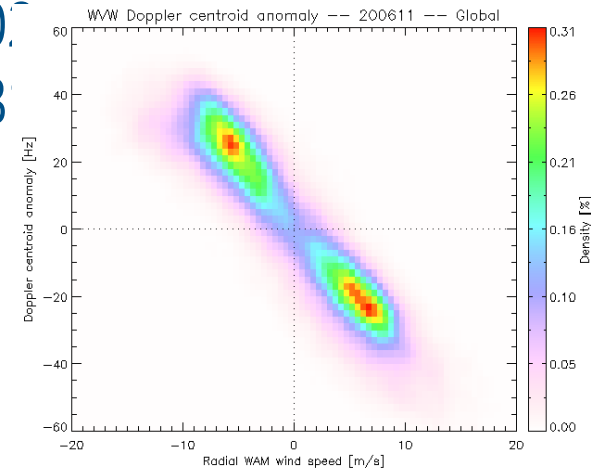

First presented at ENVISAT Cal-Val review in 2007  
published in JGR 2005 using wave mode at 23  
incidence angle.

In TGRS 2012 using ASAR wide swath across  
various incidence angles and polarisations

First order : only wind dependance

empirical law only based on wind speed and  
direction relative to radar look

**Neural Network  
training**

**CDOP\_23 = f(wind speed/direction)**

# Gulf stream, Agulhas current, North brazil current monitoring demonstration

Supersites for systematic acquisition and processing of ASAR Wide Swath scenes (400km width)

data available on [soprano.cls.fr](http://soprano.cls.fr) (current section)  
in average 2 pass over the same area every 3 days at mid latitude

## Gulf stream (North Carolina)
