## IDEAS+ WP

## TD3370

## Status

## TD3370.1

## Pandora versus OMI

- All available Pandora data have been collected (see figure)
- The historic calibration data for all Pandoras have been re-evaluated
- The data have been re-processed and report TD3370-1.2 is being written.

## TD3370.2 Brewer versus OMI

See presentation Alberto Redondas

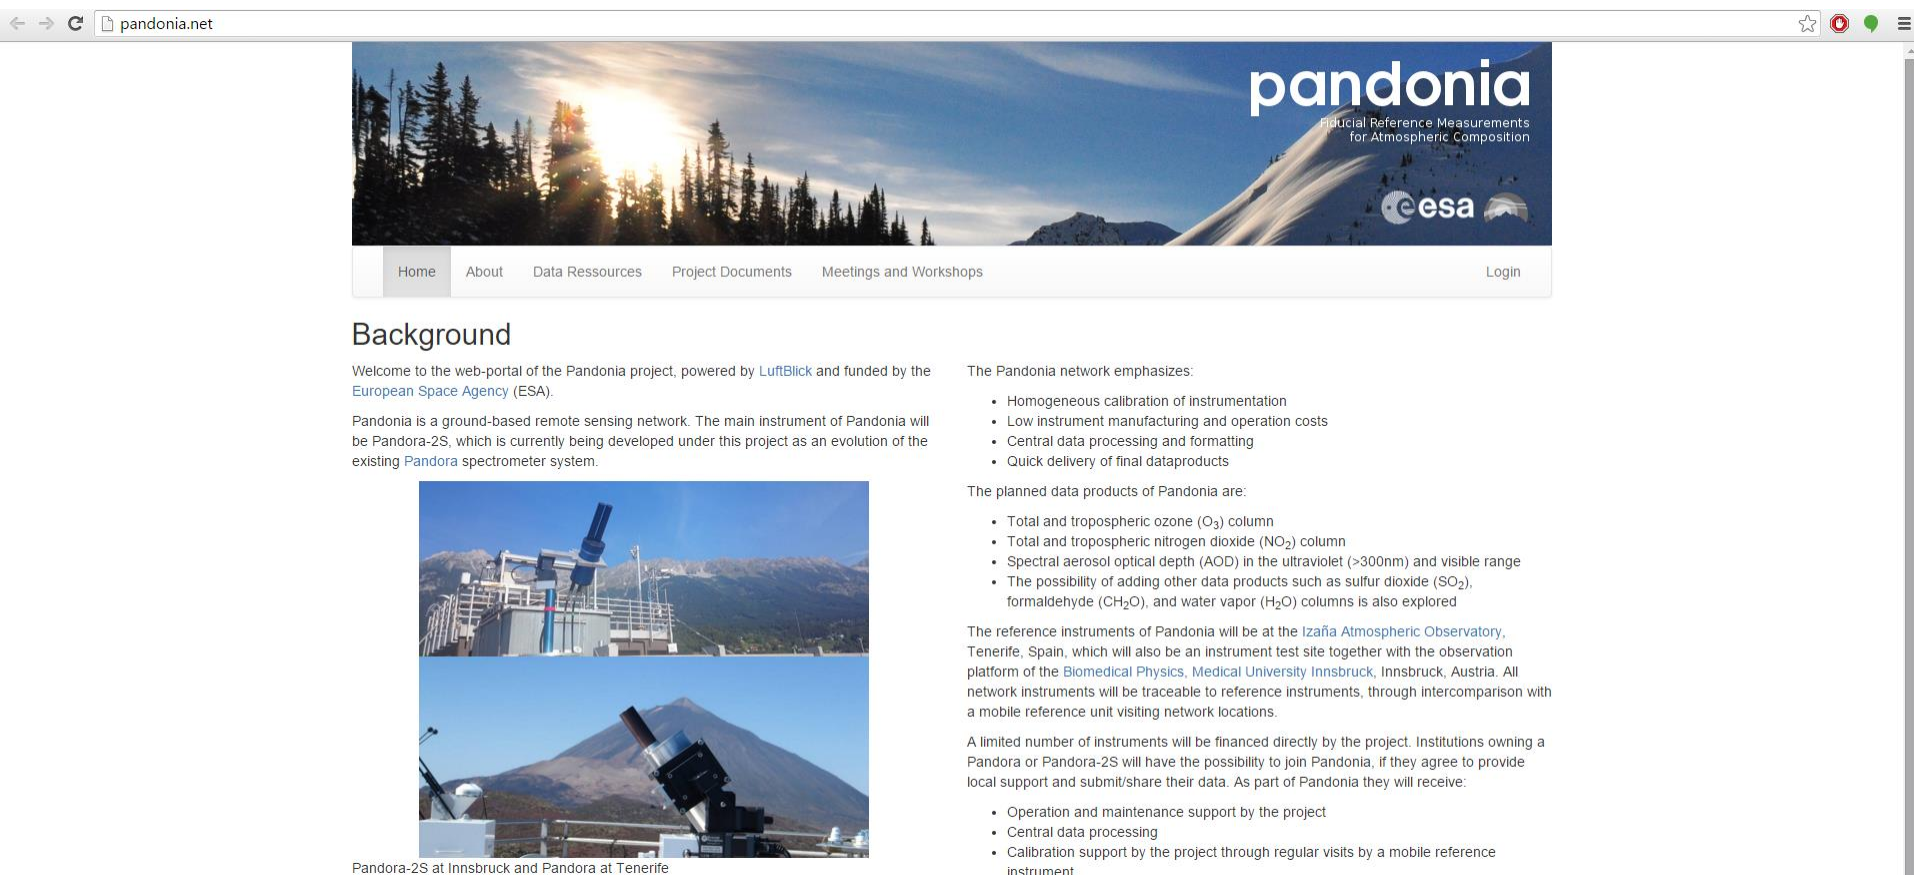

## TD3370.4 Pandora-2S units (2+1)

**Status:** The are expect to arrive at Innsbruck on 16 Dec 2015. We expect the calibration to be done before the end of the year.

## TD3370.3 Pandonia webpage developments

<http://www.pandonia.net/>

Adapted to match format of SPPA Projects (template 2015-9-15)

The screenshot shows the Pandonia website in a browser window. The browser's address bar displays "pandonia.net". The website's header features a large banner image of a snowy mountain peak with the text "pandonia" and "Official Reference Measurements for Atmospheric Composition" below it. The ESA logo is also present. A navigation menu includes links for Home, About, Data Ressources, Project Documents, Meetings and Workshops, and a Login button. The main content area is titled "Background" and contains a welcome message, a description of the Pandonia project, and two photographs of the Pandora-2S instrument at different locations. To the right of the background text, there are two bulleted lists: one for the network's emphases and another for the planned data products. Below these lists, there is a paragraph about the reference instruments and another about the project's financing and data sharing policies, followed by a final bulleted list of support provided to participating institutions.

### Background

Welcome to the web-portal of the Pandonia project, powered by LuftBlick and funded by the European Space Agency (ESA).

Pandonia is a ground-based remote sensing network. The main instrument of Pandonia will be Pandora-2S, which is currently being developed under this project as an evolution of the existing Pandora spectrometer system.

Pandora-2S at Innsbruck and Pandora at Tenerife

The Pandonia network emphasizes:

- Homogeneous calibration of instrumentation
- Low instrument manufacturing and operation costs
- Central data processing and formatting
- Quick delivery of final dataproducts

The planned data products of Pandonia are:

- Total and tropospheric ozone ( $O_3$ ) column
- Total and tropospheric nitrogen dioxide ( $NO_2$ ) column
- Spectral aerosol optical depth (AOD) in the ultraviolet ( $>300nm$ ) and visible range
- The possibility of adding other data products such as sulfur dioxide ( $SO_2$ ), formaldehyde ( $CH_2O$ ), and water vapor ( $H_2O$ ) columns is also explored

The reference instruments of Pandonia will be at the Izaña Atmospheric Observatory, Tenerife, Spain, which will also be an instrument test site together with the observation platform of the Biomedical Physics, Medical University Innsbruck, Innsbruck, Austria. All network instruments will be traceable to reference instruments, through intercomparison with a mobile reference unit visiting network locations.

A limited number of instruments will be financed directly by the project. Institutions owning a Pandora or Pandora-2S will have the possibility to join Pandonia, if they agree to provide local support and submit/share their data. As part of Pandonia they will receive:

- Operation and maintenance support by the project
- Central data processing
- Calibration support by the project through regular visits by a mobile reference instrument

## Web service architecture

- Ubuntu 14.04 based operational and development platform
- Webserver: nginx 1.9.x (operational), apache 2.4.x (development)
- Web-framework: django (based on python); some PHP scripts
- Database server: PostgreSQL 9.4
- Fully automated data delivery, processing, registration, QA, validation, ... (python, bash scripts)
- Primary server online since Jan 2013; no outages
- Data display and download tool functional with advanced features (e.g. zoom), but not intuitive to use yet
- Data volume ~4 TB (includes all L1 - L3b and all NASA data)
- Daily average data volume per station/instrument/spectrometer: 100 MB
- Data processing time including QA: 1 h
- Daily backlog processing check (for late delivery data): 5 days
- Daily match with overpass data (sync from AVDC)
- Generation/delivery/analysis of monitoring data every 3 min.
- Thread safe parallel processing sessions

- NO<sub>2</sub> data from the 2 Innsbruck Pandoras, 3 Dec 2015 (clear sky)
- “Flat plane” sunrise and sunset at 6:50 and 15:20 UT respectively
- Real sunrise and sunset at 9:20 and 14:20 UT respectively (mountains)
- Extremely good overlap of the two instruments

## Spatial comparison

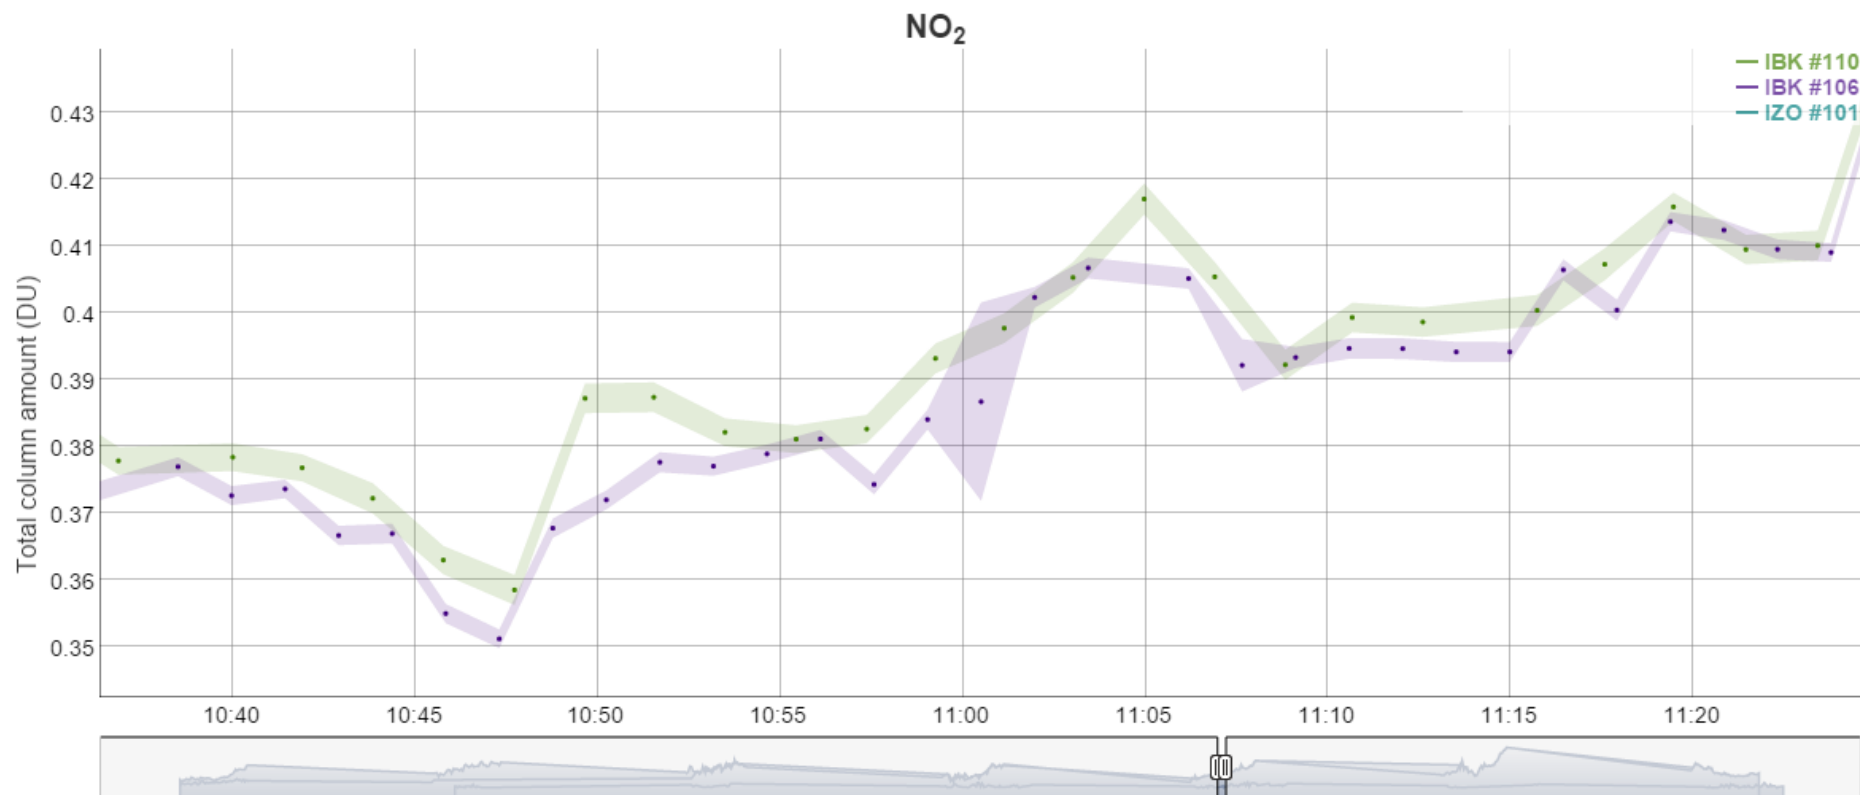

Zoom vertical axis: click & drag vertical  
Zoom time axis: click & drag horizontal

Zoom all: double-click  
Pan: shift-click&drag

- Shaded areas are the noise in the data
- “Homogeneity” for NO<sub>2</sub> about 0.01DU (excellent!)

<http://live.pandonia.net/>

- 2min data upload tested using Innsbruck units
- This still has to be optimized to handle more instruments (currently we do “too much processing”)

# LUFTBLICK

IDEAS+ development updates

IDEAS+ L1 Meeting

2015-12-8, PMOD-WRC, Davos, Switzerland

<http://live.pandonia.net/?avg=1>

Near real time data averaging and comparison with OMI

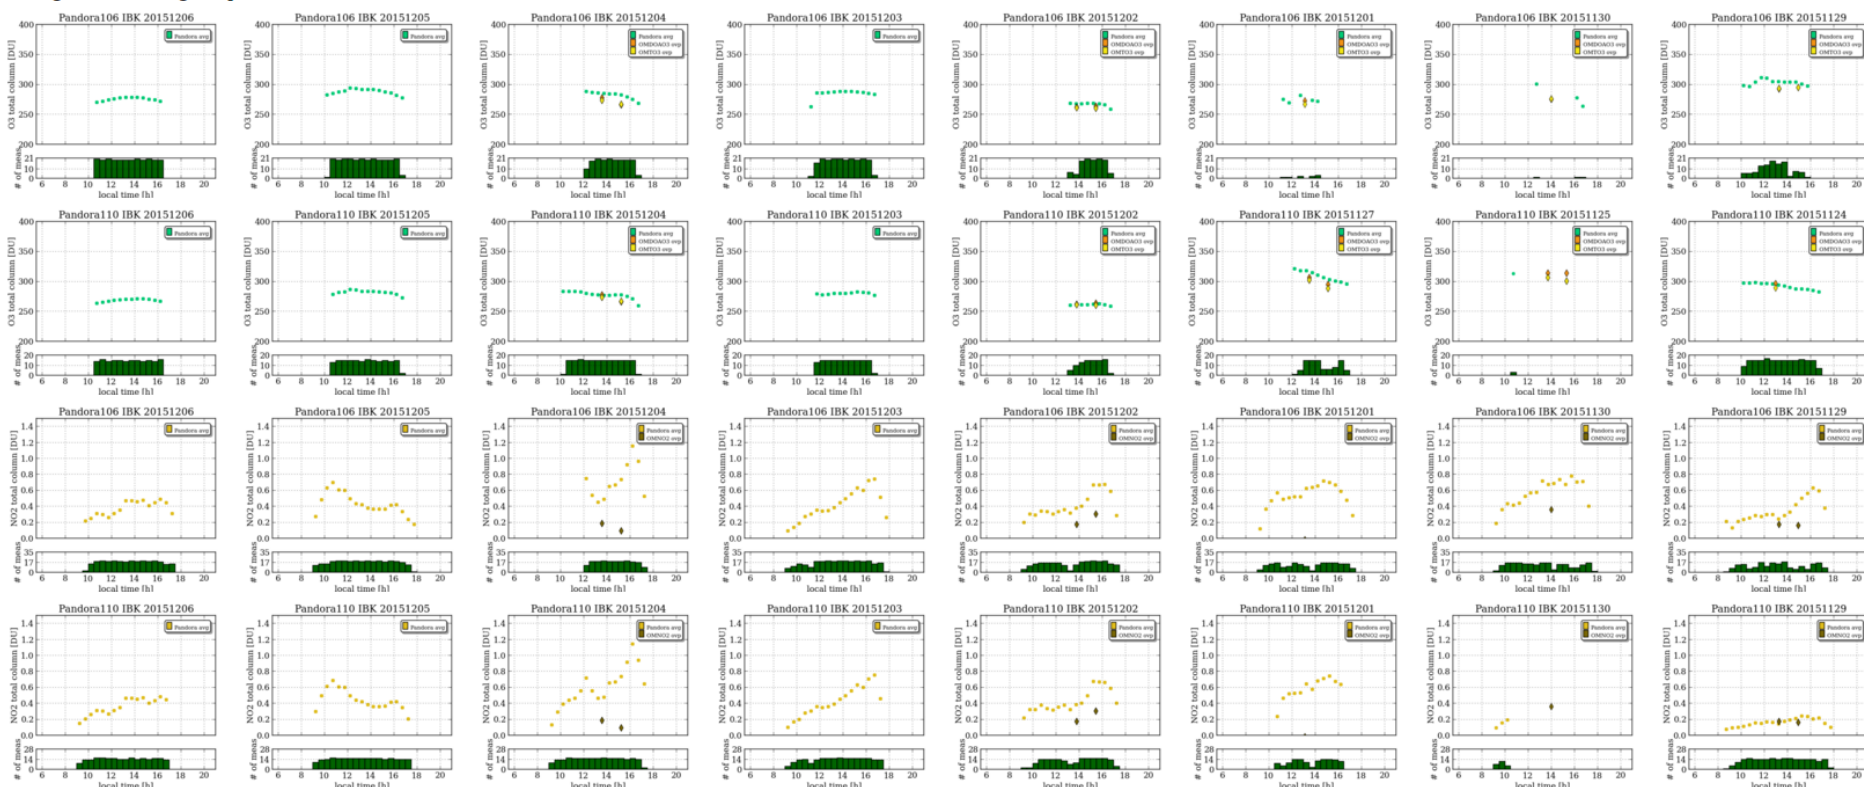

[pandonia.net/live/?avg=1](http://live.pandonia.net/?avg=1)

## Pandonia live monitoring

Status

- INFO: Last page update: 2015-12-07 13:53:51 UTC. Next page update: 2015-12-07 19:53:51 UTC

Average data including overpass

- Figures can be picked out of the overview panel
- Currently cloud filter “too simple”; e.g does not recognize the data before sunrise or after sunset as being bad

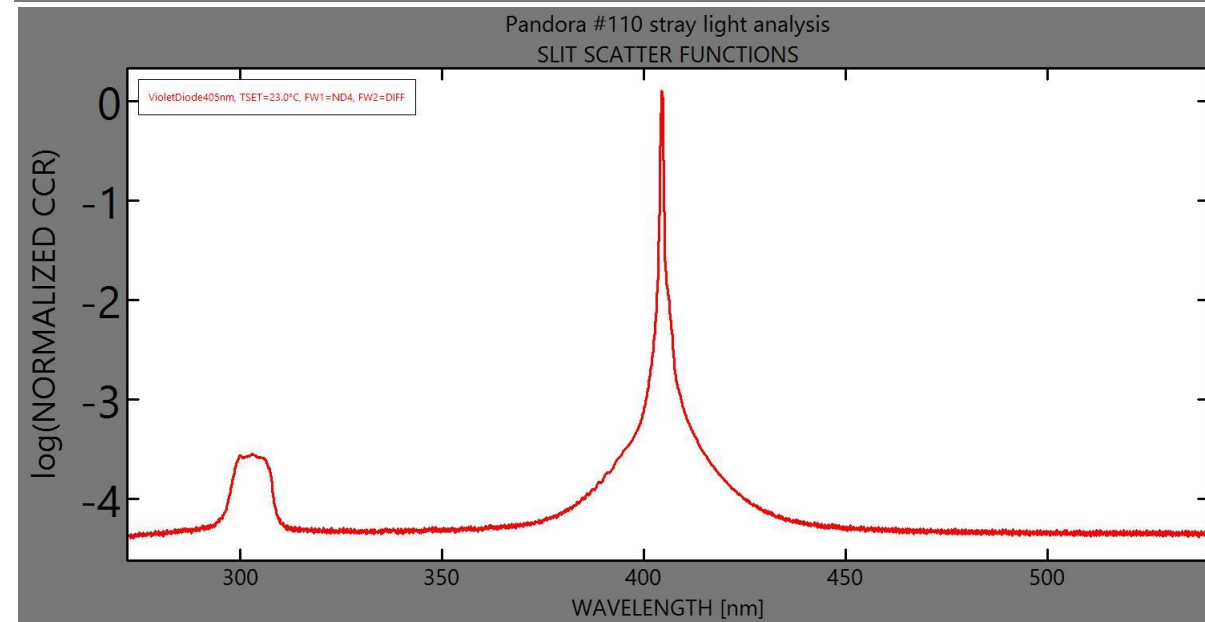

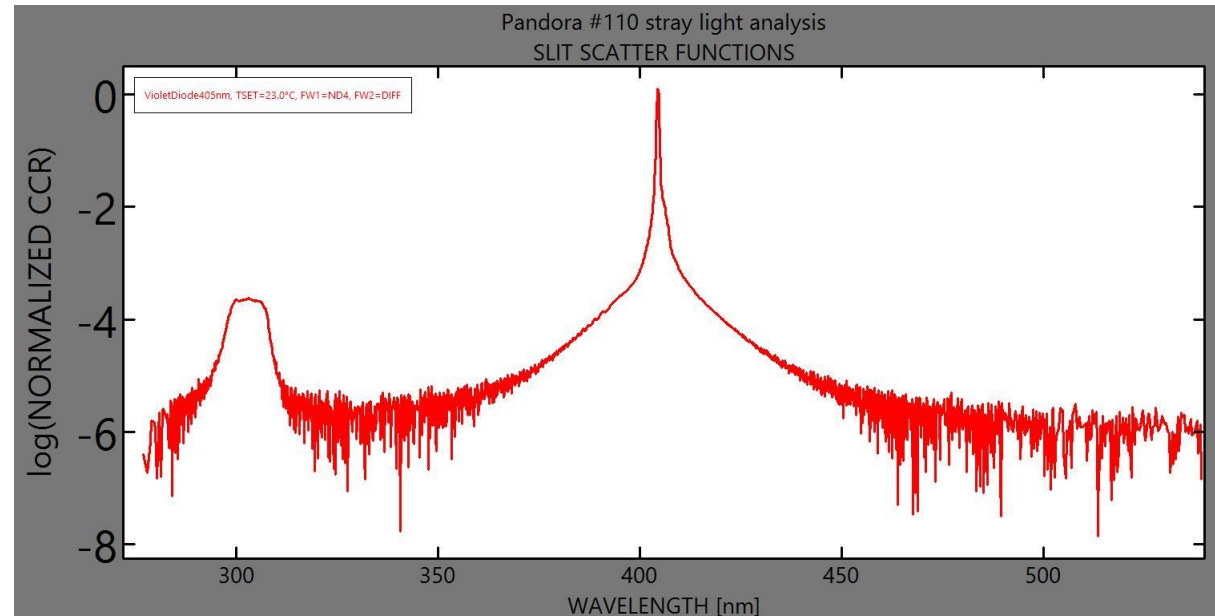

## Pandonia updates

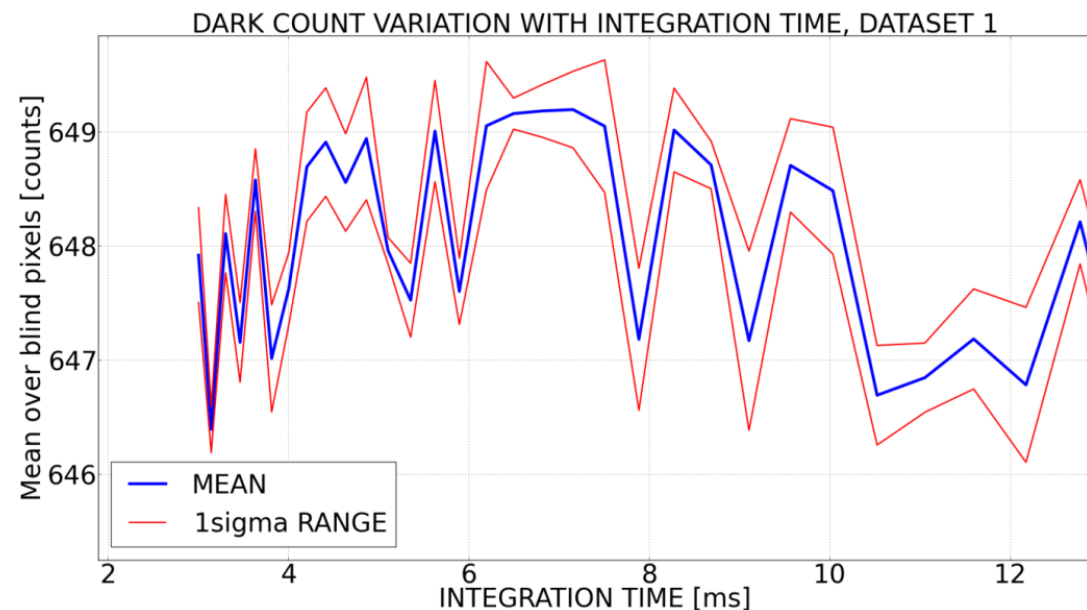

### Stray light – blind pixels

Pandora has a significant dark offset bias from measurement to measurement (mentioned in previous reports). Therefore the stray light characterization had significant problems to determine the stray light level. By using the blind pixels plus merging unsaturated and saturated data we now get excellent line spread functions.

## Dark map

- We try to create a dark map for each Pandora in order to reduce the time Pandora is “wasting” on dark measurements.
- This has shown to be much more difficult than expected. So far we were no able to explain the Pandora dark current as a function of temperature and integration time in a mathematical way.
- At this point we do not know whether the use of a dark map will be successful for Pandora.
- As an example the average over the blind pixels is shown as a function of integration time for constant temperature.

## Filterwheel 1 configuration

- We noticed that a OPEN-ND2 combination is more important than a ND1-ND1 combination.
- We changed this in Pandora 110 and for all future ones.
- Pandora 111 (Romania) still has the old combination. We will change this at the next opportunity.

# LUFTBLICK

## Tracker development

The plan is to start the IDEAS+ CCN in January.  
Status of the paperwork?

IDEAS+ development updates

IDEAS+ L1 Meeting

2015-12-8, PMOD-WRC, Davos, Switzerland

## FCT (Field calibration tool)

2 developments:

### System without fiber

- Tested at Izaña
- To be used at Izaña

### System with fiber

- Tested at Innsbruck
- To be used for mobile reference units

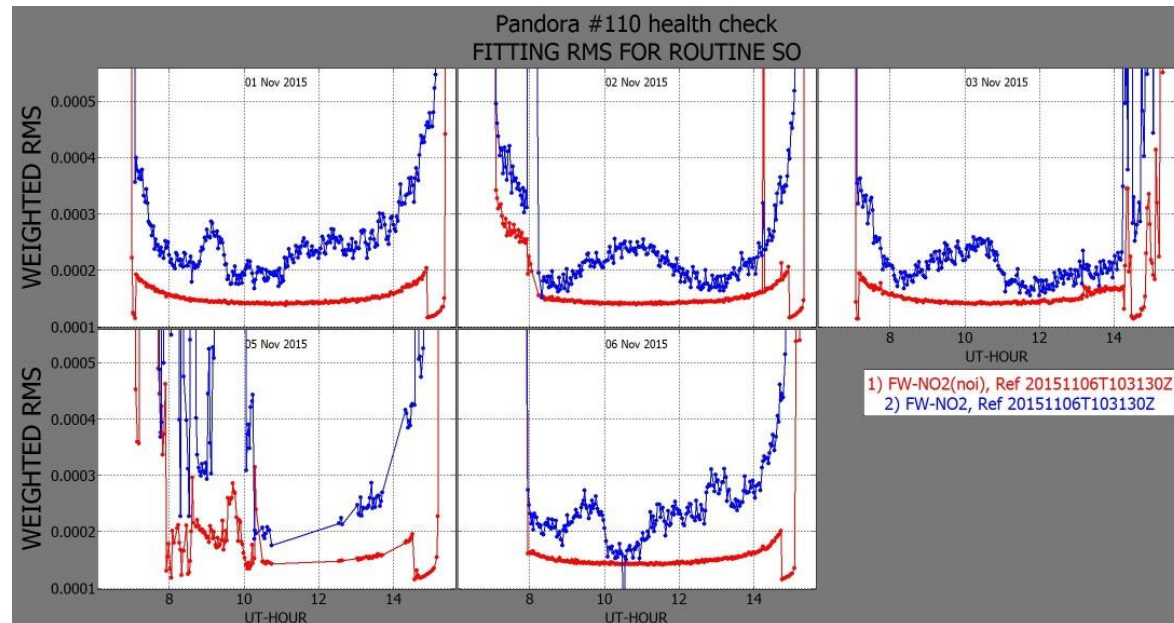

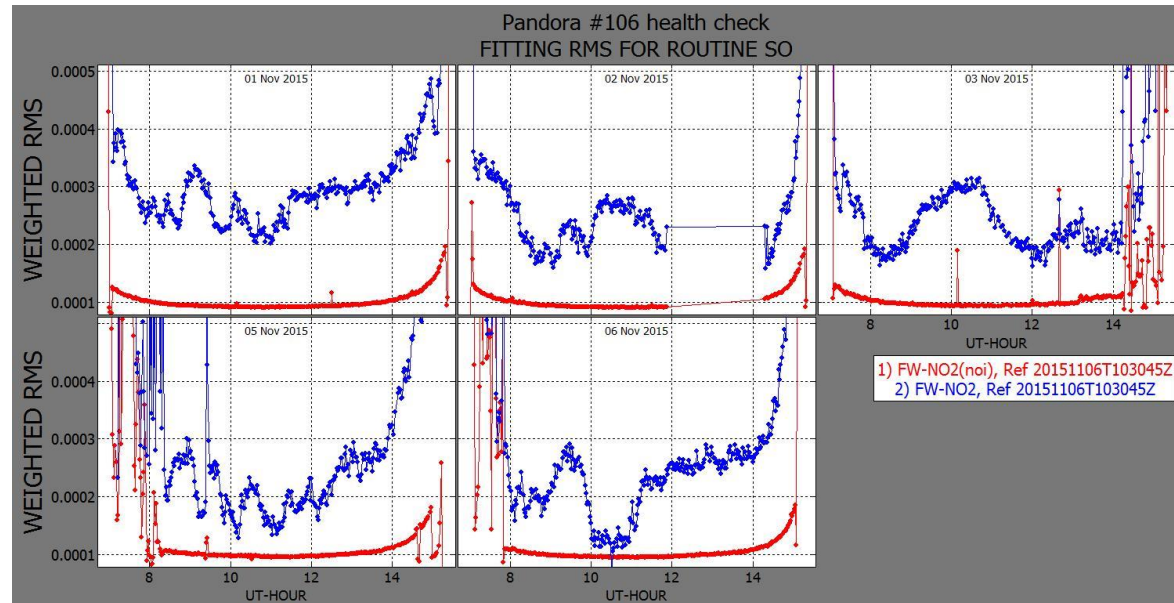

## D14: Feasibility to retrieve other trace gases

- We were able to reduce the USS (Unwanted spectral signal) by a factor of 10 with the hardware changes.
- The rms of the residuals is now very small (a few times  $1e-4$ ).
- This reduces by about a factor of ten the “temporary systematic errors” (for O3 from 5DU to 0.5DU and for NO2 from 0.07DU to 0.01DU).
- Is this good enough for weaker trace gases, e.g. HCHO?

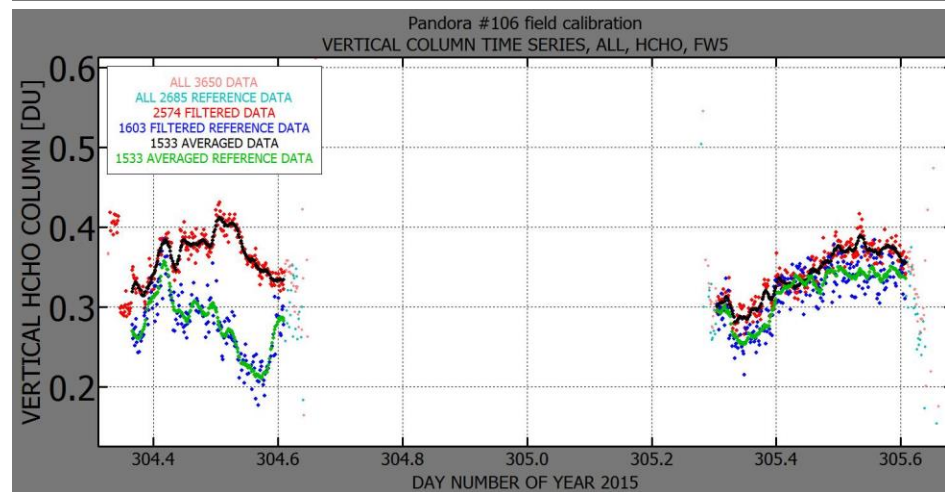

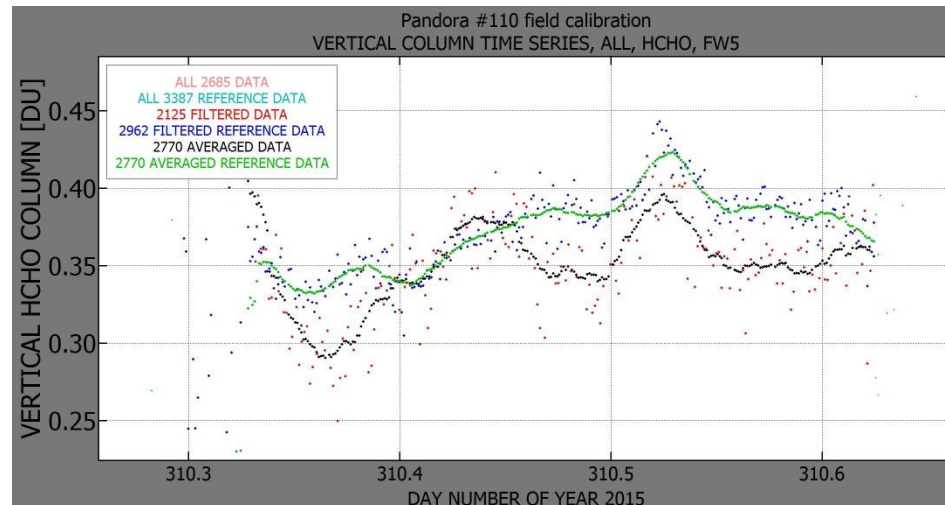

## D14: Feasibility to retrieve other trace gases

- Goal: apply same algorithm on two collocated instruments and check “homogeneity”
- Example HCHO: despite very small residuals, the differences can still be rather large
- Unclear, whether this is the USS or another effect
- rms is similar for the two days 31 Oct and 1 Nov 2015, but data agree on one day and not the other

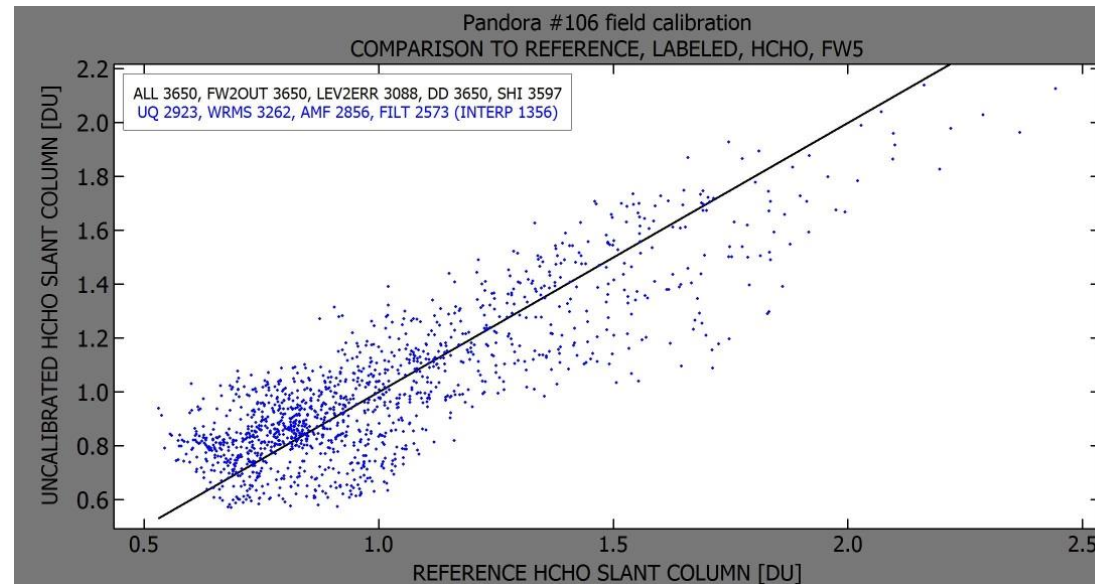

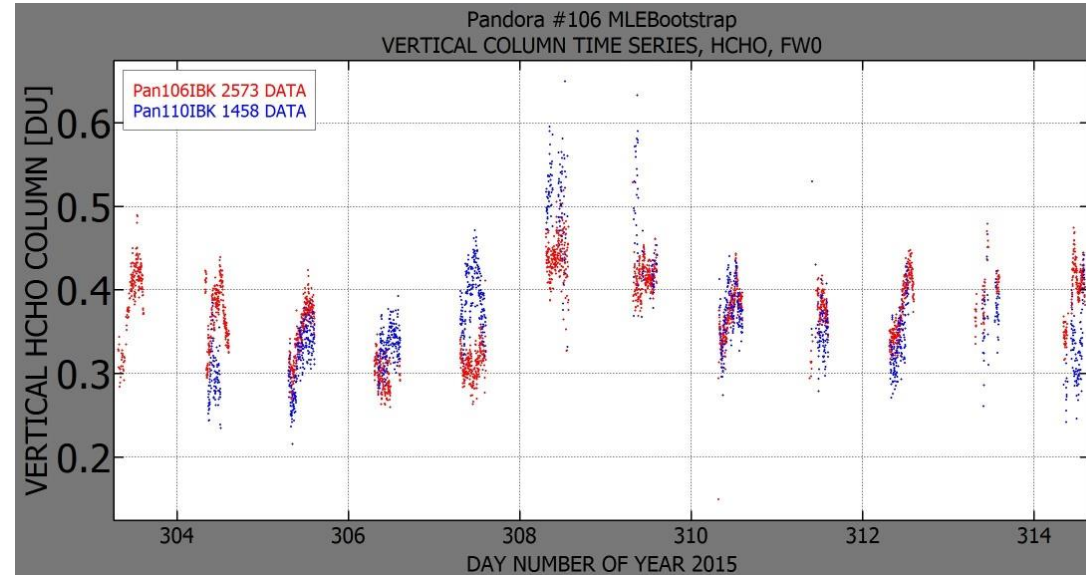

1) FW-HCHO(noi), Ref 20151101T105041Z  
2) FW-HCHO, Ref 20151101T105041Z

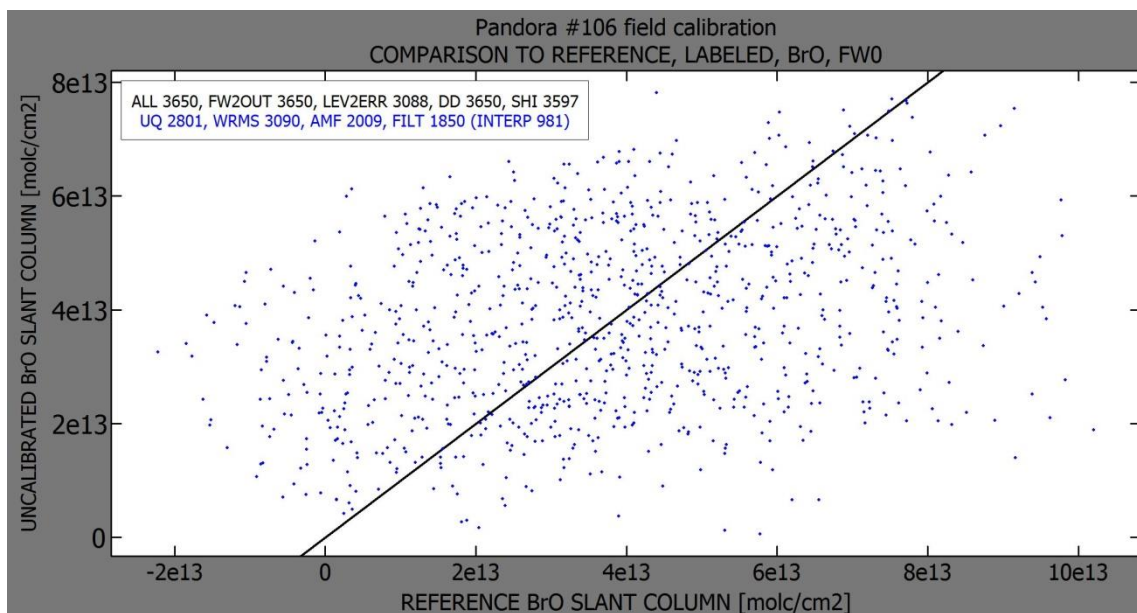

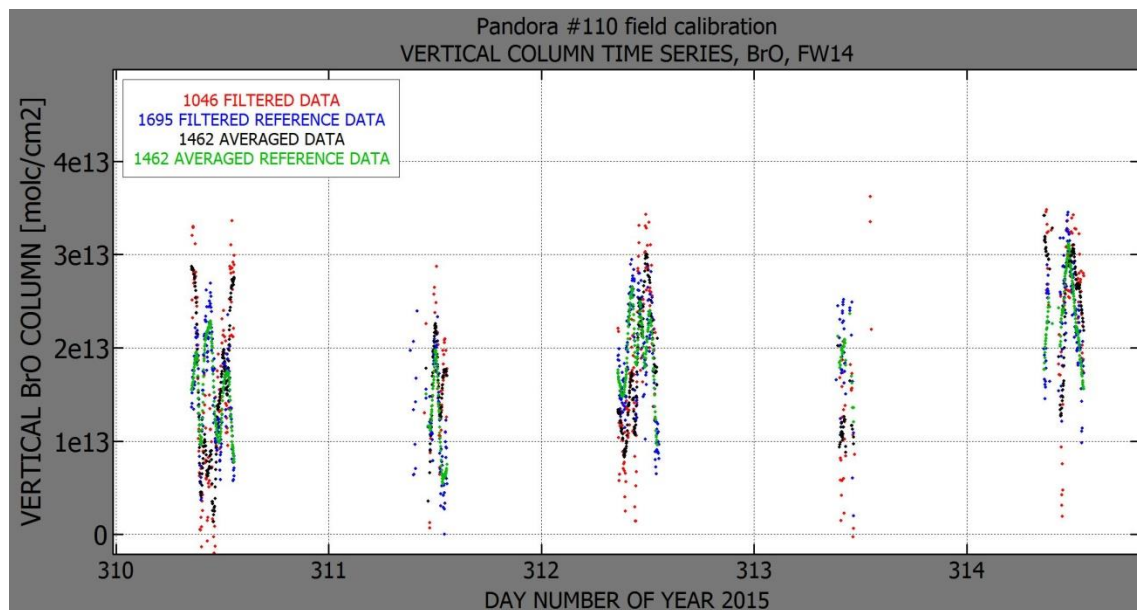

1) FW-HCHO(noi), Ref 20151101T105042Z  
2) FW-HCHO, Ref 20151101T105042Z

- We are definitely sensitive to HCHO, but there are error sources
- Noise  $\sim 0.02\text{DU}$
- Temporary systematic errors:  $\sim 0.1\text{DU}$  (drives the total uncertainty)

- BrO?
- Feasibility report will be submitted in January 2016.
- It will include homogeneity estimations for HCHO, SO<sub>2</sub>, O<sub>3</sub> + O<sub>3</sub>-temperature, NO<sub>2</sub> + NO<sub>2</sub>-temperature; possibly BrO

IDEAS+ development updates

IDEAS+ L1 Meeting

2015-12-8, PMOD-WRC, Davos, Switzerland

## Data correction steps

- Several correction steps are applied to the raw data
- The biggest challenges are “Flat fielding” and “Stray light”

Processing step	Average impact	Affected pixels impact
Dark correction	Moderate	Extreme
Enhanced pixel detection	Small	Large
Read wave correction	Small	Small
Latency correction	Moderate	Significant
Non-linearity correction	Small	Small
Temperature correction	Small	Small
Conversion to count rates	Small	Small
Flat fielding	Significant	Large
Stray light correction	Significant	Large
Conversion to radiances	Significant	Significant

**Small:**  $\varepsilon < 0.4\%$

**Moderate:**  $0.4\% < \varepsilon < 2\%$

**Significant:**  $2\% < \varepsilon < 10\%$

**Large:**  $10\% < \varepsilon < 50\%$

**Extreme:**  $\varepsilon > 50\%$

## Dark correction

- Dark count (signal at no light input) is caused by thermal electrons and electronic offset.
- It depends on the exposure time and the CCD-temperature.
- It varies over the CCD.
- It is only measured occasionally. Therefore a dark count model is used in the data correction.

c2001000\_20152101159, Wed 29 Jul 2015, 11:58:17  
L0 Dark, CCUMODE=3, TCCD=-21.2°C, TEXP=1000ms  
NBIN=1, NSAT=3, NENH=[5, 1], MIN=17, MAX=4095

## Enhanced pixel detection

- Pixels with physically impossible enhanced values are detected and flagged.
- The reason for such pixels can be effects in the readout electronics or cosmic rays events.

## Read wave correction

- EPIC's readout electronics add a small sinusoidal wave to the image, which varies in amplitude and phase from image to image.
- The read wave correction removed this feature from the data.

## Latency effect

- “Low signals being read after high signals are biased high!”
- The same input read from the bottom left corner (left panel) or the top right corner (right panel).

FRAMES 1900 & 1901, UNCORRECTED (SMOOTHED)

FRAMES 1900 & 1901, CORRECTED (SMOOTHED)

## Non-linearity correction

- *“Double input does not produce double signal”*
- EPIC is very linear! The non-linearity correction is below 0.2% over the whole range of counts.

## Temperature correction

- “EPIC is slightly more sensitive, when it is warmer.”
- EPIC temperature dependence is very small.

## Flat fielding

- “Flat input does not produce flat signal”
- Flat field response is combination of different physical effect: vignetting, etaloning, surface inhomogeneity and PRNU (pixel response non uniformity)
- EPIC’s “non-flatness” is significant, therefore the flat field correction is the most critical part in the EPIC data correction and calibration together with the stray light correction!

## Flat field calibration on orbit

- To improve the flat field correction determined from pre-launch data, images of the moon at different positions on the CCD were made.
- The moon is much “smoother” than the Earth.

## Dark side of the moon

- During new moon, EPIC can see the “Dark side of the moon” in full illumination.
- This side of the moon is “smoother” than the side pointing to the Earth.
- Some features you observe on the left panel do not “belong” to the moon and are caused by the flat field.

WITHOUT FLAT FIELD CORRECTION

FLAT FIELD FILTER 9 (764nm)

WITH FLAT FIELD CORRECTION

## Stray light effect

- “Not all the light ends up where we want it to end up.”
- We want the light from a point source to end up in the corresponding pixel and the neighbor pixels, however a very significant portion of the light spreads over the entire CCD (stray light). This is described by the point spread function (PSF).
- Lab-measurements were taken with different “targets” .
- The sub-pixel target gives us the core of the PSF but the stray light disappears in the noise.

	Straight-diagonal <1%	Second neighbor ~1%	Straight-diagonal <1%	
Straight-diagonal <1%	Diagonal neighbor ~3%	Direct neighbor ~10%	Diagonal neighbor ~3%	Straight-diagonal <1%
Second neighbor ~1%	Direct neighbor ~10%	Target pixel ~30%	Direct neighbor ~10.0%	Second neighbor ~1%
Straight-diagonal <1%	Diagonal neighbor ~3%	Direct neighbor ~10%	Diagonal neighbor ~3%	Straight-diagonal <1%
	Straight-diagonal <1%	Second neighbor ~1%	Straight-diagonal <1%	

5 $\mu$ m-target (sub-pixel)

## Stray light measurements

- A circular target with radius of 17 pixels shows the stray light.
- We noticed that there is a stray light level of 10-20%!

5 $\mu$ m-target (sub-pixel)

SET 319, FILTER 8 (MERGED, SMOOTHED)

## Ghost image

- A significant part of EPIC's stray light comes from reflections between the CCD and the filters producing a "ghost image".
- A major problem in the calibration was to distinguish between features that "belong" to the illumination beam and features from EPIC.

From EPIC  
From Input

## Point spread function

- The ghost image “moves out” of the CCD faster than the target pixel.

## Stray light level

- The amount of stray light varies from filter to filter with 11-14% stray light level for filters 1 to 6 (between 317 and 551nm) and a maximum of 20% for filter 8 (680nm).
- There are large uncertainty bars!

## Stray light correction

EPIC has a significant amount of stray light, therefore the stray light correction is the most critical part in the EPIC data correction and calibration together with the flat field correction!

The effect of stray light on the EPIC data is that small signals (from clear scenes) are biased high, while large signals (from cloudy scenes) are bias low. Hence the image contrast is reduced. This is not seen “by eye” in the images, but has significant impact on the derived data products.

The stray light effect is stronger for the visible filters than for the UV filter, since...

- ...the dynamic range in the visible is stronger (see next slide).
- ...the stray light level for filters 7 to 10 is higher.

Once the PSF is determined for each of the 4 million pixels, a numerically sophisticated stray light correction algorithm is applied, which e.g. includes the inversion of a huge  $4e6 \times 4e6$  elements diagonally dominant matrix.

The EPIC stray light correction is not implemented yet, i.e. affects the EPIC data products as of now.

## Dynamic range

- Images for 317 and 779nm, normalized to the darkest scenes in the center of the CCD.
- Ratio bright scenes (thick clouds) over dark scenes (clear sky over non-reflective ground) is up to 4 at 317nm and up to 50 at 779nm.
- Therefore the stray light has more effect in the visible!

**7 Sept 2015, 106 seconds apart**

FILTER 1, 317nm

NORMALIZED TO DARKEST SCENES

FILTER 10, 779nm

NORMALIZED TO DARKEST SCENES

## Geolocation and regridding

- Telemetry pointing information accuracy is  $\sim 2$ arcsec ( $\sim 16$ km)
- To achieve better accuracy, 'Geolocation' is applied to the data in each filter
- First the centroid ellipse is found (see figure) and then a longitude-latitude grid is created
- Finally data from different channels are shifted to a common grid
- Measurements from 2 filters are 27s apart (Earth rotates 0.5km/s on equator!)

## Channels

**Ozone and SO<sub>2</sub>: total column**

**Aerosol properties: aerosol index, aerosol optical thickness, aerosol height**

**Cloud & surface properties: cloud fraction, cloud height, surface albedo**
