

Cloud screening method particularly feasible for snow cover mapping

Sari Metsämäki
Finnish Environment Institute (SYKE)

LPVE Workshop
ESA, Esrin
28-30 Jan 2014

Motivation

- Need for cloud screening algorithm in ESA DUE-GlobSnow project (2009 -)
- Project team could not identify a suitable method for Envisat/AATSR, particularly for fractional snow mapping purposes
- Undetected clouds usually lead to false snow identification
- Very conservative cloud mask may reduce the area for snow mapping
 - Problems over snow-covered boreal forests and at the edges of snow-covered terrain or at thin snow cover
- Official AATSR cloud mask (provided in level 1b) presents severe false cloud commissions over land areas

Framework for method development

- No need to identify all (small/semi-transparent) clouds in confident snow-free areas
- Cloud screening is targeted, not cloud classification → binary information, no classes, no probabilities
- Must be relatively simple and computationally fast
- Must be applicable for Northern Hemisphere, no regional/local tuning
- Must not confuse between fractional snow and clouds (it's the fractional snow we want to see!)
- Should work particularly over seasonally snow-covered areas and throughout the potential snow season

Major features of SCDA2.0

- Simple Cloud Detection Algorithm
- Designed to work with only a few spectral bands
 - common for Terra/MODIS, Envisat/AATSR, ERS-2/ATSR-2, NPP Suomi/VIIRS → R550, R1.6, BT3.7, BT11, BT12
- Based on empirically determined thresholds for single bands and their ratios
 - Driven by BT11-BT3.7
 - Ratio NDSI / R550 important in avoiding false cloud commissions
 - Several other test for BT12, R550 and NDSI

Occasional cloud omissions in summer months for some cloud types

Way forward

- Improvements are allways welcome! Issue with clouds is not solved...
- On-going work: better detection of summertime clouds
 - Reference image approach is investigated (based on *SCAmod* FSC retrieval method)
 - Expansion of teaching data set for decision rules
- Cloud shadows currently not considered in SCDA2.0
 - 1-2 pixels buffering does not completely solve this problem
- In situ observations on cloudiness could help the method development and validation: e.g. sky-cameras
- Need of proper cloud screening method for snow mapping purposes from Sentinel-3 SLSTR
 - SCDA2.0 is a good basis for that

Thank you for your attention!
